#### 16CAU601B UNIX/LINUX PROGRAMMING

#### **LECTURE PLAN**

S.No	Lecturer Duration(Hrs)	Topics to be Covered	Support Materials
		UNIT I	
1	1	What is Linux/Unix Operating Systems	R1:12-15,W1
2	1	Difference between linux/unix and other operating systems	R1:16-20
3	1	Features and Architecture	R2:15-22
4	1	Various Distributions available in the market	R2:23-27
		Installation, Booting and shutdown process	R1:25-30
5	1	Recapitulation and discussion of Important Questions	
	Total No. of H	ours planned for Unit-I : 5 Hours	

S.No	Lecturer	Topics to be Covered	Support Materials
	<b>Duration(Hrs)</b>		
		UNIT II	
1	1	System processes (an overview)	R3:53-58
2	1	External and internal commands	R3:65-69
3	1	Creation of partitions in OS	R3:70-77,W2
4	1	Processes and its creation phases, Fork, Exec, wait	R3:78-86,W3
5	1	Recapitulation and discussion of Important Questions	
	Total No. of I	Hours planned for Unit II : 5 Hours	

S.No	Lecturer Duration(Hrs)	Topics to be Covered	Support Materials
	Duration(1115)	UNIT III	
1	1	Types of Users, Creating users	R4:63-71
2	1	Granting rights	R4:72-77
		User management commands	
3	1	File quota and various file systems available	R4:78-87
4	1	File System Management and Layout, File permissions	R4:88-96,J1
5	1	Login process, Managing Disk Quotas, Links (hard links, symbolic links)	R4:103-112
6	1	Recapitulation and discussion of Important Questions	
	Total No. of H	lours planned for Unit III : 6 Hours	

#### **LECTURE PLAN**

S.No	Lecturer	Topics to be Covered	Support Materials					
	<b>Duration(Hrs)</b>							
	UNIT IV							
1	1	Shell introduction and Shell Scripting	R4:129-138					
2	1	What is shell and various type of shell	R4:139-143, W4					
3	1	Various editors present in Linux Different modes of operation in vi editor	R4:143-148					
4	1	What is shell script, Writing and executing the shell script	R4:149-157					
5	1	Shell variable (user defined and system variables)	R4:158-166					
6	1	Recapitulation and Discussion of important Questions						
	Total No. of I	Hours planned for Unit IV : 6 Hours						

#### **LECTURE PLAN**

S.No	Lecturer Duration(Hrs)	Topics to be Covered	Support Materials						
	UNIT V								
1	1	System calls, Using system calls	R4:167-173						
2	1	Pipes and Filters, Decision making in Shell Scripts (If else, switch),	W5,R4:174-177						
3	1	Loops in shell, Functions	R4:178-186						
4	1	Utility programs (cut, paste, join, tr, uniq utilities), Pattern matching utility (grep)	R4:187-195						
5	1	Recapitulation and Discussion of important Questions							
6	1	Discussion of Previous ESE papers							
7	1	Discussion of Previous ESE papers							
8	1	Discussion of Previous ESE papers							
		Total No. of Hours planned for Unit V : 8 Hours							
	TOTAL PLANNED HOURS : 30

### Unit-I

Introduction What is Linux/Unix Operating systems, Difference between linux/unix and other operating systems, Features and Architecture, Various Distributions available in the market, Installation, Booting and shutdown process

#### What is Unix Operating systems

UNIX is an operating system which was first developed in the 1960s, and has been under constant development ever since. By operating system, we mean the suite of programs which make the computer work. It is a stable, multi-user, multi-tasking system for servers, desktops and laptops.

UNIX systems also have a graphical user interface (GUI) similar to Microsoft Windows which provides an easy to use environment. However, knowledge of UNIX is required for operations which aren't covered by a graphical program, or for when there is no windows interface available, for example, in a telnet session.

#### What is Linux Operationg System?

Linux is a <u>Unix</u>-like, open source and community-developed <u>operating system</u> for computers, servers, mainframes, mobile devices and embedded devices. It is supported on almost every major computer platform including x86, ARM and <u>SPARC</u>, making it one of the most widely supported operating systems.

#### Difference between Linux/Unix and other operating systems

	Linux	Unix
Cost	Linux can be freely distributed, downloaded freely, distributed through magazines, Books etc. There are priced versions for Linux also, but they are normally cheaper than Windows.	Different flavors of Unix have different cost structures according to vendors
Development and	Linux is developed by Open Source development i.e. through	Unix systems are divided into various other flavors, mostly developed by AT&T as well

	Linux	Unix
Distribution	sharing and collaboration of code and features through forums etc and it is distributed by various vendors.	as various commercial vendors and non- profit organizations.
Manufacturer	Linux kernel is developed by the community. Linus Torvalds oversees things.	Three bigest distributions are Solaris (Oracle), AIX (IBM) & HP-UX Hewlett Packard. And Apple Makes OSX, an unix based os
User	Everyone. From home users to developers and computer enthusiasts alike.	Unix operating systems were developed mainly for mainframes, servers and workstations except OSX, Which is designed for everyone. The Unix environment and the client-server program model were essential elements in the development of the Internet
Usage	Linux can be installed on a wide variety of computer hardware, ranging from mobile phones, tablet computers and <u>video game</u> <u>consoles</u> , to mainframes and supercomputers.	The UNIX operating system is used in internet servers, workstations & PCs. Backbone of the majority of finance infastructure and many 24x365 high availability solutions.
File system support	Ext2, Ext3, Ext4, Jfs, ReiserFS, Xfs, Btrfs, FAT, <u>FAT32, NTFS</u>	jfs, gpfs, hfs, hfs+, ufs, xfs, zfs format
Text mode interface	BASH (Bourne Again SHell) is the Linux default shell. It can support multiple command interpreters.	Originally the Bourne Shell. Now it's compatible with many others including BASH, Korn & C.
What is it?	Linux is an example of Open Source software development and Free Operating System (OS).	Unix is an operating system that is very popular in universities, companies, big enterprises etc.
GUI	Linux typically provides two GUIs, <u>KDE and Gnome</u> . But there are millions of alternatives such as LXDE, Xfce, Unity, Mate, twm, ect.	Initially Unix was a command based OS, but later a GUI was created called Common Desktop Environment. Most distributions now ship with Gnome.
Price	Free but support is available for a price.	Some free for development use (Solaris) but support is available for a price.

	Linux	Unix
Security	Linux has had about 60-100 viruses listed till date. None of them actively spreading nowadays.	A rough estimate of UNIX viruses is between 85 -120 viruses reported till date.
Threat detection and solution	In case of Linux, threat detection and solution is very fast, as Linux is mainly community driven and whenever any Linux user posts any kind of threat, several developers start working on it from different parts of the world	Because of the proprietary nature of the original Unix, users have to wait for a while, to get the proper bug fixing patch. But these are not as common.
Processors	Dozens of different kinds.	x86/x64, Sparc, Power, Itanium, PA-RISC, PowerPC and many others.
Examples	<u>Ubuntu</u> , <u>Fedora</u> , Red Hat, Debian, Archlinux, Android etc.	OS X, Solaris, All Linux
Architectures	Originally developed for Intel's x86 hardware, ports available for over two dozen CPU types including ARM	is available on PA-RISC and Itanium machines. Solaris also available for x86/x64 based systems.OSX is PowerPC(10.0- 10.5)/x86(10.4)/x64(10.5-10.8)
Inception	Inspired by MINIX (a Unix-like system) and eventually after adding many features of GUI, Drivers etc, Linus Torvalds developed the framework of the OS that became LINUX in 1992. The LINUX kernel was released on 17th September, 1991	In 1969, it was developed by a group of AT&T employees at Bell Labs and Dennis Ritchie. It was written in "C" language and was designed to be a portable, multi-tasking and multi-user system in a time-sharing configuration.

#### **Features of UNIX**

High reliability, scalability and powerful features make UNIX a popular operating system, according to Intel. Now beyond its 40th year as of 2010, UNIX is the backbone of many data centers including the Internet. Big players using UNIX include Sun Microsystems, Apple Inc., Hewlett-Packard and AT&T, which is the original parent company of UNIX. The Open Group owns all UNIX specifications and the trademark, which are freely accessible and available over the Internet.

#### **Multitasking and Portability**

The main features of UNIX include multiuser, multitasking and portability capabilities. Multiple users access the system by connecting to points known as terminals. Several users can run multiple programs or processes simultaneously on one system. UNIX uses a high-level language that is easy to comprehend, modify and transfer to other machines, which means you can change language codes according to the requirements of new hardware on your computer. You, therefore, have the flexibility to choose any hardware, modify the UNIX codes accordingly and use UNIX across multiple architectures.

#### The Kernel and the Shell

The hub of a UNIX operating system, the kernel manages the applications and peripherals on a system. Together, the kernel and the shell carry out your requests and commands. You communicate with your system through the UNIX shell, which translates to the kernel. When you turn on your terminal, a system process starts that overlooks your inputs. When you enter your password, the system associates the shell program with your terminal. The shell allows you to customize options even if you are not technically savvy. For example, if you partially type a command, the shell anticipates the command for which you are aiming and displays the command for you. The UNIX shell is a program that gives and displays your prompts and, in conjunction with the kernel, executes your commands. The shell even maintains a history of the commands you enter, allowing you to reuse a command by scrolling through your history of commands.

#### **Files and Processes**

All the functions in UNIX involve either a file or a process. Processes are executions of programs, while files are collections of data created by you. Files may include a document,

programming instructions for the system or a directory. UNIX uses a hierarchical file structure in its design that starts with a root directory--signified by the forward slash (/). The root is followed by its subdirectories, as in an inverted tree, and ends with the file. In the example "/Demand/Articles/UNIX.doc," the main directory "Demand" has a subdirectory "Articles," which has a file "UNIX.doc."

# **Features of Linux**

Following are some of the important features of Linux Operating System.

- **Portable** Portability means softwares can works on different types of hardwares in same way.Linux kernel and application programs supports their installation on any kind of hardware platform.
- **Open Source** Linux source code is freely available and it is community based development project. Multiple teams works in collaboration to enhance the capability of Linux operating system and it is continuously evolving.
- **Multi-User** Linux is a multiuser system means multiple users can access system resources like memory/ ram/ application programs at same time.
- **Multiprogramming** Linux is a multiprogramming system means multiple applications can run at same time.
- **Hierarchical File System** Linux provides a standard file structure in which system files/ user files are arranged.
- **Shell** Linux provides a special interpreter program which can be used to execute commands of the operating system. It can be used to do various types of operations, call application programs etc.
- Security Linux provides user security using authentication features like password protection/ controlled access to specific files/ encryption of data.

# **ARCHITECTURE OF UNIX**

There are two important divisions in UNIX operating system architecture.

1.Kernel

2.Shell

In simple words you can say –

- Kernal interacts with the machine's hardware
- Shell interacts with the user

### THE KERNEL:

The kernel of UNIX is the hub (or core) of the UNIX operating system. Kernel is a set of routines mostly written in C language.

User programs that need to access the hardware (like hard disk or terminal) use the services of the Kernel, which performs the job on the user's behalf.

User interacts with the Kernal by using System calls. Kernel allocates memory and time to programs and handles the file store and communications in response to system calls.

As an illustration of the way that the unix shell and the kernel work together, suppose a user types *mv myfile myfile1* (which has the effect of renaming the file myfile). The unix shell

searches the file store for the file containing the program mv, and then requests the kernel, through system calls, to execute the program *mv* on *myfile*. When the process *mv myfile* has finished running, the unix shell then returns the UNIX prompt to the user, indicating that it is waiting for further commands.

# THE SHELL:

UNIX Shell acts as a medium between the user and the kernel in unix system. When a user logs in, the login program checks the username and password and then starts another program called the shell.

Computers don't have any inherent capability of translating commands into action. This requires a command line interpreter (CLI) and this is handled by the "Outer Part" of the operating system i.e. Shell. It interprets the commands the user types in and arranges for them to be carried out. In every unix system, the user can customize his own shell, and users can use different shells on the same machine.

The shell keeps a list of the commands you have typed in. If you need to repeat a command, use the cursor keys to scroll up and down the list or type history for a list of previous commands.

### Various Distributions of UNIX available in the market

Flavors that are available commercially (read: sold) include:

Solaris – Sun Microsystems' implementation, of which there are different kinds available: these are Solaris OS for SPARC platforms, Solaris OS for x86 platforms, and Trusted Solaris for both SPARC & x86 platforms; the latest version is Solaris 10 OS

AIX – short for Advanced Interactive eXecutive; IBM's implementation, the latest release of which, is the AIX 5L version 5.2.

SCO UnixWare and OpenServer – are implementations derived from the original AT&T Unix® source code acquired by the Santa Cruz Operation Inc. from Novell, and later on bought by Caldera Systems; the latest versions are UnixWare 7.1.3 and OpenServer 5.0.7

BSD/OS – the Berkeley Software Distribution (BSD) Unix implementation from Wind River; its latest version is the BSD/OS 5.1 Internet Server Edition

IRIX – the proprietary version of Unix from Silicon Graphics Inc.; the latest release of which is IRIX 6.5

HP-UX - short for Hewlett-Packard UniX; the latest version is the HP-UX 11i

Tru64 UNIX – the Unix operating environment for HP AlphaServer systems; Tru64 UNIX v5.1B-1 is the latest version

Mac OS – Mac operating system from Apple Computer Inc. having a Unix core; the latest version is the Mac OS X Panther

### Various Distributions of LINUX available in the market

#### Debian

Debian is one of the oldest distributions out there, and some newer, more popular distributions are based on the Debian software. For instance, Ubuntu is a newer Linux distribution based on the Debian architecture. Debian has more than 1,000 volunteers, which makes it very versatile.

#### Fedora and Red Hat

Red Hat was developed several years ago, and it was known as one of the easiest of the Linux distributions to learn, if you were new to the operating system. Fedora has a great support community, and it's known as one of the better business suites out there.

#### Ubuntu

For users who are unfamiliar with Linux but want to learn, Ubuntu is the closest to Windows and user-friendly you can get. Ubuntu is one of the babies of the Linux family. It's not that old, but

its popularity has grown. Ubuntu has a very "Windows-like" interface, so it's most popular for its ease of use for Windows users who want to migrate to a Linux platform.

#### Linux Mint

Mint has one of the coolest interfaces for customizing a desktop. Mint's graphics and desktop reminds most old Linux users of the classic GNOME interface. Mint is the alternative to Ubuntu. Most Ubuntu fans who are unhappy with the way Ubuntu is heading moved to Mint.

### **Installation of UNIX**

Use this procedure as the starting point for installing WebLogic Integration - Business Connect on the supported UNIX operating systems.

Steps

1. Create a user account for WebLogic Integration - Business Connect (connect, for example) as the home directory for the application. For example, you can use one of the following as a home directory:

/opt/connect

/usr/local/connect

2. Determine the device name of your CD-ROM drive.

The installation CD has a standard ISO-9660 (High Sierra) file system with Rock Ridge extensions.

- 3. Determine how much RAM your server has. You need to enter this information during the installation routine.
- 4. See the installation procedure for your operating system:
- Installing on Hewlett-Packard HP-UX
- Installing on IBM AIX
- Installing on Sun Solaris

We can use the install.sh command:

### **Booting of UNIX**

Unix boot process has these main phases:

• Basic hardware detection (memory, disk, keyboard, mouse, and the like).

• Executing the firmware system initialization program (happens automatically).

• Locating and running the initial boot program (by the firmware boot program), usually from a predetermined location on disk. This program may perform additional hardware checks prior to loading the kernel.

• Locating and starting the Unix kernel (by the first-stage boot program). The kernel image file to execute may be determined automatically or via input to the boot program.

• The kernel initializes itself and then performs final, high-level hardware checks, loading device drivers and/or kernel modules as required.

• The kernel starts the init process, which in turn starts system processes (daemons) and initializes all active subsystems. When everything is ready, the system begins accepting user logins.

# Shutting Down of Unix System

From time to time, you will need to shut thesystem down. This is necessary for scheduled maintenance, running diagnostics, hardware changes or additions, and other administrative tasks.

During a clean system shutdown, the following actions take place:

• All users are notified that the system will be going down, preferably giving them some reasonable advance warning.

• All running processes are sent a signal telling them to terminate, allowing them time to exit gracefully, provided the program has made provisions to do so.

• All subsystems are shut down gracefully, via the commands they provide for doing so.

• All remaining users are logged off, and remaining processes are killed.

• Filesystem integrity is maintained by completing all pending disk updates.

• Depending on the type of shutdown, the system moves to single-user mode, the processor is halted, or the system is rebooted.

# Installation of Linux

- 1. Download the Linux distribution of your choice. ...
- 2. Boot into the Live CD or Live USB.
- 3. Try out the **Linux** distribution before **installing**.
- 4. Start the **installation** process.

#### 5. Create a username and password.

6. Set up the partition. Linux needs to be installed on a separate partition from any other operating systems on your computer if you intend dual booting Linux with another OS. A partition is a portion of the hard drive that is formatted specifically for that operating system.

7. **Boot into Linux.** Once the installation is finished, your computer will reboot. You will see a new screen when your computer boots up called "GNU GRUB". This is a boot loader that handles Linux installations. Check your hardware.

**8.Check your hardware.** Most hardware should work out of the box with your Linux distro, though you may need to download some additional drivers to get everything working. Some hardware requires proprietary drivers to work correctly in Linux.

# **Booting of Linux**

1.BIOS

- BIOS stands for Basic Input/Output System
- Performs some system integrity checks
- 2. MBR
- MBR stands for Master Boot Record.
- It is located in the 1st sector of the bootable disk. Typically /dev/hda, or /dev/sda
- 3. GRUB
- GRUB stands for Grand Unified Bootloader.
- If you have multiple kernel images installed on your system, you can choose which one to be executed.
- As you notice from the above info, it contains kernel and initrd image.
- So, in simple terms GRUB just loads and executes Kernel and initrd images.

4. Kernel

- Mounts the root file system as specified in the "root=" in grub.conf
- Kernel executes the /sbin/init program
- 5. Init
- Looks at the /etc/inittab file to decide the Linux run level.
- Following are the available run levels
  - 0 halt
  - 1 Single user mode
- Typically you would set the default run level to either 3 or 5.
- 6. Runlevel programs
- When the Linux system is booting up, you might see various services getting started. For example, it might say "starting sendmail .... OK". Those are the runlevel programs, executed from the run level directory as defined by your run level.

#### **Shutdown of Linux**

Linux was not made to be shut down, but if you really must, use the **shutdown** command. After completing the shutdown procedure, the -h option will halt the system, while -r will reboot it. The **reboot** and **halt** commands are now able to invoke **shutdown** if run when the system is in run levels 1-5, and thus ensure proper shutdown of the system, but it is a bad habit to get into, as not all UNIX/Linux versions have this feature. If your computer does not power itself down, you should not turn off the computer until you see a message indicating that the system is halted or finished shutting down, in order to give the system the time to unmount all partitions. Being impatient may cause data loss.

#### POSSIBLE QUESTIONS PART B QUESTIONS (EACH QUESTION CARRIES TWO MARKS)

- 1. What are the features of Unix ?
- 2. What are the features of Linux?
- 3. What do you mean by shell in Linux?
- 4. What do you mean by kernel in Unix?.
- 5. List out the various distributions of Unix.
- 6. List out the various distributions of Linux.
- 7. What is booting in Unix?
- 8. What is utility in Unix?.

#### PART C QUESTIONS (EACH QUESTION CARRIES 6 MARKS)

- 1.Explain the difference between Unix and Linux.
- 2.Discuss the architecture of Unix.
- 3.Explain the architecture of Linux.
- 4.Discuss the various distributions of Unix and Linux.
- 5.Explain the internal and external commands in Linux.
- 6.Explain the Installation, Booting and shutdown process of Unix.

**Coimbatore – 641 021.** 

### DEPARTMENT OF COMPUTER SCIENCE, CA & IT UNIT - I : (Objective Type Multiple choice Questions each Question carries one Mark) UNIX/LINUX PROGRAMMING PART - A (Online Examination)

Questions	Opt1	opt2	opt3	opt4	KEY
computer hardware and acts as an intermediary	acceleration	Operating System	compiler	logical transcation	System
manages the execution of user programs to	resource all	work station	main frame	control program	program
	Mainframe	Mainframe			Mainframe
were the first computers used to tackle many	computer	computer	multiframe	multiframe	computer

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

# <u>UNIT – II</u>

# **SYLLABUS**

# System processes (an overview), External and internal commands, Creation of partitions in OS, Processes and its creation phases – Fork, Exec, wait

• Mode bit: Supervisor or User mode • Supervisor mode – Can execute all machine instructions – Can reference all memory locations • User mode – Can only execute a subset of instructions – Can only reference a subset of memory locations

### <u>Kernel Mode</u>

- When CPU is in **kernel mode**, the code being executed can access any memory address and any hardware resource.
- Hence kernel mode is a very privileged and powerful mode.
- If a program crashes in kernel mode, the entire system will be halted.

### <u>User Mode</u>

- When CPU is in **user mode**, the programs don't have direct access to memory and hardware resources.
- In user mode, if any program crashes, only that particular program is halted.
- That means the system will be in a safe state even if a program in user mode crashes.
- Hence, most programs in an OS run in user mode.

# SYSTEM CALLS AND SYSTEM PROGRAMS

• System calls provide an interface between the process and the operating system. System calls allow user-level processes to request some services from the operating system which process itself is not allowed to do. In handling the trap, the operating system will enter in the kernel mode, where it has access to privileged instructions, and can perform the

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

desired service on the behalf of user-level process. It is because of the critical nature of operations that the operating system itself does them every time they are needed. For example, for I/O a process involves a system call telling the operating system to read or write particular area and this request is satisfied by the operating system.

• System programs provide basic functioning to users so that they do not need to write their own environment for program development (editors, compilers) and program execution (shells). In some sense, they are bundles of useful system calls.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

	Windows	Unix
Process	CreateProcess()	fork()

	CreateFileMapping()	shmget()
	MapViewOfFile()	mmap()
Protection	SetFileSecurity()	chmod()
	InitlializeSecurityDescriptor()	umask()
	SetSecurityDescriptorGroup()	chown()

#### SYSTEM CALL

When a program in user mode requires access to RAM or a hardware resource, it must ask the kernel to provide access to that resource. This is done via something called a **system call**.

When a program makes a system call, the mode is switched from user mode to kernel mode. This is called a **context switch**.

Then the kernel provides the resource which the program requested. After that, another context switch happens which results in change of mode from kernel mode back to user mode.

Generally, system calls are made by the user level programs in the following situations:

- Creating, opening, closing and deleting files in the file system.
- Creating and managing new processes.
- Creating a connection in the network, sending and receiving packets.
- Requesting access to a hardware device, like a mouse or a printer.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

In a typical UNIX system, there are around 300 system calls. Some of them which are important ones in this context are described below.

#### SYSTEM PROGRAMS

These programs are not usually part of the OS kernel, but are part of the overall operating system.

#### **File Management**

These programs create, delete, copy, rename, print, dump, list, and generally manipulate files and directories.

#### **Status Information**

Some programs simply request the date and time, and other simple requests. Others provide detailed performance, logging, and debugging information. The output of these files is often sent to a terminal window or GUI window

#### File modification

Programs such as text editors are used to create, and modify files.

#### Communications

These programs provide the mechanism for creating a virtual connect among processes, users, and other computers. Email and web browsers are a couple examples.

#### PROCESS MANAGEMENT

#### **Process Concept**

Process is a program that is in execution. It is defined as unit of work in modern systems. A batch system executes jobs, whereas a time-shared system has user programs, or tasks. Even on a single-user system, a user may be able to run several programs at one time: a word processor, a Web browser, and an e-mail package. And even if a user can execute only one program at a time, such as on an embedded device that does not support multitasking, the operating system may need to support its own internal programmed activities, such as memory management. In many respects, all these activities are similar, so we call all of them processes.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

#### **Process in memory**

A process is more than the program code, which is sometimes known as the text section. It also includes the current activity, as represented by the value of the program counter and the contents of the processor's registers. A process generally also includes the process stack, which contains temporary data (such as function parameters, return addresses, and local variables), and a data section, which contains global variables. A process may also include a heap, which is memory that is dynamically allocated during process run time.

#### **Process in Memory**

A program is a passive entity, such as a file containing a list of instructions stored on disk (often called an executable file). In contrast, a process is an active entity, with a program counter specifying the next instruction to execute and a set of associated resources. A program becomes a process when an executable file is loaded into memory.

#### **Process State**

As a process executes, it changes state. The state of a process is defined in part by the current activity of that process. A process may be in one of the following states:

• New. The process is being created.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

• Running. Instructions are being executed.

• Waiting. The process is waiting for some event to occur (such as an I/O completion or reception of a signal).

- Ready. The process is waiting to be assigned to a processor.
- Terminated. The process has finished execution.

These names are arbitrary, and they vary across operating systems. The states that they represent are found on all systems, however. Certain operating systems also more finely delineate process states. It is important to realize that only one process can be running on any processor at any instant. Many processes may be ready and waiting, however. The state diagram corresponding to these states is presented in the following Figure.

#### **Process State Diagram**

#### **Process Control Block (PCB)**

Each process is represented in the operating system by a process control block (PCB)—also called a task control block. It contains many pieces of information associated with a specific process, including these: Process state. The state may be new, ready, running, and waiting, halted, and so on.

- **Program counter.** The counter indicates the address of the next instruction to be executed for this process.
- CPU registers. The registers vary in number and type, depending on the computer architecture. They include accumulators, index registers, stack pointers, and general-

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

purpose registers, plus any condition-code information. Along with the program counter, this state information must be saved when an interrupt occurs, to allow the process to be continued correctly afterward.

• **CPU-scheduling information.** This information includes a process priority, pointers to scheduling queues, and any other scheduling parameters.

#### **Process Control Block (PCB)**

- Memory-management information. This information may include such items as the value of the base and limit registers and the page tables, or the segment tables, depending on the memory system used by the operating system
- Accounting information. This information includes the amount of CPU and real time used, time limits, account numbers, job or process numbers, and so on.
- **I/O status information**. This information includes the list of I/O devices allocated to the process, a list of open files, and so on.

#### **THREAD**

• A thread is a flow of execution through the process code, with its own program counter, system registers and stack. A thread is also called a light weight process. Threads provide a way to improve application performance through parallelism. Threads represent a software approach to improving performance of operating system by reducing the overhead thread is equivalent to a classical process.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

• Each thread belongs to exactly one process and no thread can exist outside a process. Each thread represents a separate flow of control. Threads have been successfully used in implementing network servers and web server. They also provide a suitable foundation for parallel execution of applications on shared memory multiprocessors. Following figure shows the working of the single and multithreaded processes.

### Advantages of Thread

- Thread minimizes context switching time.
- Use of threads provides concurrency within a process.
- Efficient communication.
- Economy- It is more economical to create and context switch threads.
- Utilization of multiprocessor architectures to a greater scale and efficiency.

#### **Types of Thread**

- Threads are implemented in following two ways
- User Level Threads -- User managed threads
- Kernel Level Threads -- Operating System managed threads acting on kernel, an operating system core.
- User Level Threads

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

• In this case, application manages thread management kernel is not aware of the existence of threads. The thread library contains code for creating and destroying threads, for passing message and data between threads, for scheduling thread execution and for saving and restoring thread contexts. The application begins with a single thread and begins running in that thread.

### **ADVANTAGES**

- Thread switching does not require Kernel mode privileges.
- User level thread can run on any operating system.
- Scheduling can be application specific in the user level thread.
- User level threads are fast to create and manage.

#### **DISADVANTAGES**

- In a typical operating system, most system calls are blocking.
- Multithreaded application cannot take advantage of multiprocessing.

#### Kernel Level Threads

In this case, thread management done by the Kernel. There is no thread management code in the application area. Kernel threads are supported directly by the operating system. Any

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

application can be programmed to be multithreaded. All of the threads within an application are supported within a single process.

The Kernel maintains context information for the process as a whole and for individuals threads within the process. Scheduling by the Kernel is done on a thread basis. The Kernel performs thread creation, scheduling and management in Kernel space. Kernel threads are generally slower to create and manage than the user threads.

#### **ADVANTAGES**

• Kernel can simultaneously schedule multiple threads from the same process on multiple processes.

• If one thread in a process is blocked, the Kernel can schedule another thread of the same process.

• Kernel routines themselves can multithreaded.

#### **DISADVANTAGES**

• Kernel threads are generally slower to create and manage than the user threads.

• Transfer of control from one thread to another within same process requires a mode switch to the Kernel.

#### **Multithreading Models**

Some operating system provides a combined user level thread and Kernel level thread facility. Solaris is a good example of this combined approach. In a combined system, multiple threads within the same application can run in parallel on multiple processors and a blocking system call need not block the entire process. Multithreading models are three types

- Many too many relationships.
- Many to one relationship.
- One to one relationship.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

#### Many to Many Model

- In this model, many user level threads multiplex to the Kernel thread of smaller or equal numbers. The number of Kernel threads may be specific to either a particular application or a particular machine.
- Following diagram shows the many to many models. In this model, developers can create as many user threads as necessary and the corresponding Kernel threads can run in parallels on a multiprocessor.

#### Many to One Model

- Many to one model maps many user level threads to one Kernel level thread. Thread management is done in user space. When thread makes a blocking system call, the entire process will be blocks. Only one thread can access the Kernel at a time, so multiple threads are unable to run in parallel on multiprocessors.
- If the user level thread libraries are implemented in the operating system in such a way that system does not support them then Kernel threads use the many to one relationship modes.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

#### **One to One Model**

- There is one to one relationship of user level thread to the kernel level thread. This model provides more concurrency than the many to one model. It is also another thread to run when a thread makes a blocking system call. It supports multiple thread to execute in parallel on microprocessors.
- Disadvantage of this model is that creating user thread requires the corresponding Kernel thread. OS/2, windows NT and windows 2000 use one to one relationship model.

#### THREADING ISSUES OPERATING SYSTEMS

#### 1. The fork() and exec() System Calls

- If one thread in a program calls fork(), does the new process duplicate all threads, or is the new process single-threaded? Some UNIX systems have chosen to have two versions of fork(), one that duplicates all threads and another that duplicates only the thread that invoked the fork() system call.
- If a thread invokes the exec() system call, the program specified in the parameter to exec () will replace the entire process-including all threads.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

### 2. Cancellation

- Thread cancellation is the task of terminating a thread before it has completed. For example, if multiple threads are concurrently searching through a database and one thread returns the result, the remaining threads might be canceled.
- > A thread that is to be canceled is often referred to as the **target thread**.
- > Cancellation of a target thread may occur in two different scenarios:
  - Asynchronous cancellation. One thread immediately terminates the target thread.
  - **Deferred cancellation.** The target thread periodically checks whether it should terminate, allowing it an opportunity to terminate itself in an orderly fashion.
- The difficulty with cancellation occurs in situations where resources have been allocated to a canceled thread or where a thread is canceled while in the midst of updating data it is sharing with other threads.

### 3. Signal Handling

- A signal is used in UNIX systems to notify a process that a particular event has occurred. All signals, whether synchronous or asynchronous, follow the same pattern:
- > A signal is generated by the occurrence of a particular event.
- > A generated signal is delivered to a process.
- > Once delivered, the signal must be handled.
- Examples of synchronous signals include illegal memory access and division by 0. If a running program performs either of these actions, a signal is generated.
- Every signal has a default signal handler that is run by the kernel when handling that signal. This default action can be overridden by a user defined signal handler that is called to handle the signal.
- Handling signals in single-threaded programs is straightforward: signals are always delivered to a process. However, delivering signals is more complicated in

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

multithreaded programs, where a process may have several threads. Where, then, should a signal be delivered?

- ➢ In general the following options exist:
  - Deliver the signal to the thread to which the signal applies.
  - Deliver the signal to every thread in the process.
  - Deliver the signal to certain threads in the process.
  - Assign a specific thread to receive all signals for the process.

# 4<u>. Thread Pools</u>

- The first issue concerns the amount of time required to create the thread prior to servicing the request, together with the fact that this thread will be discarded once it has completed its work.
- The second issue is more troublesome: if we allow all concurrent requests to be serviced in a new thread, we have not placed a bound on the number of threads concurrently active in the system. Unlimited threads could exhaust system resources, such as CPU time or memory. One solution to this problem is to use a thread pool.
- The general idea behind a thread pool is to create a number of threads at process startup and place them into a pool, where they sit and wait for work.
- > Thread pools offer these benefits:
  - Servicing a request with an existing thread is usually faster than waiting to create a thread.
  - A thread pool limits the number of threads that exist at any one point. This is particularly important on systems that cannot support a large number of concurrent threads.

# 5. Thread-Specific Data

• Threads belonging to a process share the data of the process. Indeed, this sharing of data provides one of the benefits of multithreaded programming.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- However, in some circumstances, each thread might need its own copy of certain data.
   We will call such data thread specific data.
- For example, in a transaction-processing system, we might service each transaction in a separate thread. Furthermore, each transaction might be assigned a unique identifier. To associate each thread with its unique identifier, we could use thread-specific data.

# PROCESS SCHEDULING

## **Definition**

- The process scheduling is the activity of the process manager that handles the removal of the running process from the CPU and the selection of another process on the basis of a particular strategy.
- Process scheduling is an essential part of a Multiprogramming operating system. Such operating systems allow more than one process to be loaded into the executable memory at a time and loaded process shares the CPU using time multiplexing.

# **Scheduling Queues**

Scheduling queues refers to queues of processes or devices. When the process enters into the system, then this process is put into a job queue. This queue consists of all processes in the system. The operating system also maintains other queues such as device queue. Device queue is a queue for which multiple processes are waiting for a particular I/O device. Each device has its own device queue.

This figure shows the queuing diagram of process scheduling.

- Queue is represented by rectangular box.
- The circles represent the resources that serve the queues.
- The arrows indicate the process flow in the system.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

Queues are of two types

- Ready queue
- Device queue

A newly arrived process is put in the ready queue. Processes waits in ready queue for allocating the CPU. Once the CPU is assigned to a process, then that process will execute. While executing the process, any one of the following events can occur.

- The process could issue an I/O request and then it would be placed in an I/O queue.
- The process could create new sub process and will wait for its termination.

• The process could be removed forcibly from the CPU, as a result of interrupt and put back in the ready queue.

## **Two State Process Model**

Two state process model refers to running and non-running states which are described below.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

S.N.	State & Description
1	<b>Running</b> When new process is created by Operating System that process enters into the system as in the running state.
2	Not Running Processes that are not running are kept in queue, waiting for their turn to execute. Each entry in the queue is a pointer to a particular process. Queue is implemented by using linked list. Use of dispatcher is as follows. When a process is interrupted, that process is transferred in the waiting queue. If the process has completed or aborted, the process is discarded. In either case, the dispatcher then selects a process from the queue to execute.

# **Schedulers**

Schedulers are special system software which handles process scheduling in various ways. Their main task is to select the jobs to be submitted into the system and to decide which process to run. Schedulers are of three types

- Long Term Scheduler
- Short Term Scheduler
- Medium Term Scheduler

## Long Term Scheduler

It is also called job scheduler. Long term scheduler determines which programs are admitted to the system for processing. Job scheduler selects processes from the queue and loads them into memory for execution. Process loads into the memory for CPU scheduling. The primary objective of the job scheduler is to provide a balanced mix of

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

jobs, such as I/O bound and processor bound. It also controls the degree of multiprogramming. If the degree of multiprogramming is stable, then the average rate of process creation must be equal to the average departure rate of processes leaving the system.

On some systems, the long term scheduler may not be available or minimal. Timesharing operating systems have no long term scheduler. When process changes the state from new to ready, then there is use of long term scheduler.

# Short Term Scheduler

- It is also called CPU scheduler. Main objective is increasing system performance in accordance with the chosen set of criteria. It is the change of ready state to running state of the process. CPU scheduler selects process among the processes that are ready to execute and allocates CPU to one of them.
- Short term scheduler also known as dispatcher, execute most frequently and makes the fine grained decision of which process to execute next. Short term scheduler is faster than long term scheduler.

## Medium Term Scheduler

Medium term scheduling is part of the swapping. It removes the processes from the memory. It reduces the degree of multiprogramming. The medium term scheduler is incharge of handling the swapped out-processes.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

Running process may become suspended if it makes an I/O request. Suspended processes cannot make any progress towards completion. In this condition, to remove the process from memory and make space for other process, the suspended process is moved to the secondary storage. This process is called swapping, and the process is said to be swapped out or rolled out. Swapping may be necessary to improve the process mix.

## **Comparison between Scheduler**

S.N.	Long Term Scheduler	Short Term Scheduler	Medium Term Scheduler
1	It is a job scheduler	It is a CPU scheduler	It is a process swapping scheduler.
2	Speed is lesser than short term scheduler	Speed is fastest among other two	Speed is in between both short and long term scheduler.
3	It controls the degree of multiprogramming	It provides lesser control over degree of multiprogramming	It reduces the degree of multiprogramming.
4	It is almost absent or minimal in time sharing system	It is also minimal in time sharing system	It is a part of Time sharing systems.
5	It selects processes from pool and loads them into memory for execution	It selects those processes which are ready to execute	It can re-introduce the process into memory and execution can be continued.

# **SCHEDULING (PREEMPTIVE AND NONPREEMPTIVE)**

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- *A* final issue to be considered with multithreaded programs concerns communication between the kernel and the thread library, which may be required by the many-to-many and two-level models.
- Such coordination allows the number of kernel threads to be dynamically adjusted to help ensure the best performance.

# **General Goals**

#### <u>Fairness</u>

Fairness is important under all circumstances. A scheduler makes sure that each process gets its fair share of the CPU and no process can suffer indefinite postponement. Note that giving equivalent or equal time is not fair. Think of *safety control* and *payroll* at a nuclear plant.

#### **Policy Enforcement**

The scheduler has to make sure that system's policy is enforced. For example, if the local policy is safety then the *safety control processes* must be able to run whenever they want to, even if it means delay in *payroll processes*.

## **Efficiency**

Scheduler should keep the system (or in particular CPU) busy cent percent of the time when possible. If the CPU and all the Input/Output devices can be kept running all the time, more work gets done per second than if some components are idle.

## **Response Time**

A scheduler should minimize the response time for interactive user.

## <u>Turnaround</u>

A scheduler should minimize the time batch users must wait for an output.

#### **Throughput**

A scheduler should maximize the number of jobs processed per unit time.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

# Preemptive Vs Non preemptive Scheduling

The Scheduling algorithms can be divided into two categories with respect to how they deal with clock interrupts.

## Non preemptive Scheduling

A scheduling discipline is non preemptive if, once a process has been given the CPU, the CPU cannot be taken away from that process.

Following are some characteristics of non preemptive scheduling

- 1. In non preemptive system, short jobs are made to wait by longer jobs but the overall treatment of all processes is fair.
- 2. In non preemptive system, response times are more predictable because incoming high priority jobs cannot displace waiting jobs.
- 3. In non preemptive scheduling, a scheduler executes jobs in the following two situations.
  - a. When a process switches from running state to the waiting state.
  - b. When a process terminates.

## **Preemptive Scheduling**

- A scheduling discipline is preemptive if, once a process has been given the CPU can taken away.
- The strategy of allowing processes that are logically runable to be temporarily suspended is called Preemptive Scheduling and it is contrast to the "run to completion" method.

## Schedule:

A Process Scheduler schedules different processes to be assigned to the CPU based on particular scheduling algorithms. There are six popular process scheduling algorithms which we are going to discuss in this chapter –

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- First-Come, First-Served (FCFS) Scheduling
- Shortest-Job-Next (SJN) Scheduling
- Priority Scheduling
- Shortest Remaining Time
- Round Robin(RR) Scheduling
- Multiple-Level Queues Scheduling
- These algorithms are either **non-preemptive or preemptive**. Non-preemptive algorithms are designed so that once a process enters the running state; it cannot be preempted until it completes its allotted time, whereas the preemptive scheduling is based on priority where a scheduler may preempt a low priority running process anytime when a high priority process enters into a ready state.

## First Come First Serve (FCFS)

- Jobs are executed on first come, first serve basis.
- It is a non-preemptive, pre-emptive scheduling algorithm.
- Easy to understand and implement.
- Its implementation is based on FIFO queue.
- Poor in performance as average wait time is high.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

Process	Arrival Time	Execute Time	Service Time
PO	0	5	0
P1	1	3	5
P2	2	8	8
P3	3	6	16

P	0	P1	P2	P3	
-					
0	5	8		16	22

Wait time of each process is as follows -

Process	Wait Time : Service Time - Arrival Time
P0	0 - 0 = 0
P1	5 - 1 = 4
P2	8 - 2 = 6
Р3	16 - 3 = 13

Average Wait Time: (0+4+6+13) / 4 = 5.75

## Shortest Job Next (SJN)

- This is also known as **shortest job first**, or SJF
- This is a non-preemptive, pre-emptive scheduling algorithm.
- Best approach to minimize waiting time.
- Easy to implement in Batch systems where required CPU time is known in advance.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- Impossible to implement in interactive systems where required CPU time is not known.
- The processer should know in advance how much time process will take.

Process	Arrival Time	Execute Time	Service Time
PO	0	5	3
P1	1	3	0
P2	2	8	16
P3	3	6	8

P	1	PO	P3	P2	:
0	3	8		16	22

Wait time of each process is as follows -

Process	Wait Time : Service Time - Arrival Time
PO	3 - 0 = 3
P1	0 - 0 = 0
P2	16 - 2 = 14
Р3	8 - 3 = 5

Average Wait Time: (3+0+14+5) / 4 = 5.50

## **Priority Based Scheduling**

- Priority scheduling is a non-preemptive algorithm and one of the most common scheduling algorithms in batch systems.
- Each process is assigned a priority. Process with highest priority is to be executed first and so on.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- Processes with same priority are executed on first come first served basis.
- Priority can be decided based on memory requirements, time requirements or any other resource requirement.

Process	Arrival Time	Execute Time	Priority	Service Time
PO	0	5	1	9
P1	1	3	2	6
P2	2	8	1	14
P3	3	6	3	0

PB		P1	PO	P2
0	6	9	14	22

Wait time of each process is as follows -

Process	Wait Time : Service Time - Arrival Time
PO	9 - 0 = 9
P1	6 - 1 = 5
P2	14 - 2 = 12
Р3	0 - 0 = 0

Average Wait Time: (9+5+12+0) / 4 = 6.5

# Shortest Remaining Time

- Shortest remaining time (SRT) is the preemptive version of the SJN algorithm.
- The processor is allocated to the job closest to completion but it can be preempted by a newer ready job with shorter time to completion.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- Impossible to implement in interactive systems where required CPU time is not known.
- It is often used in batch environments where short jobs need to give preference.

## Round Robin Scheduling

- Round Robin is the preemptive process scheduling algorithm.
- Each process is provided a fix time to execute, it is called a **quantum**.
- Once a process is executed for a given time period, it is preempted and other process executes for a given time period.
- Context switching is used to save states of preempted processes.

~ ·	-
Quantum	(= J

	PO	P1	P2	P3	PO	P2	P3	P2
 0	3	6	9	12	14	15	 7 20	 0 22

Wait time of each process is as follows -

Process	Wait Time : Service Time - Arrival Time
P0	(0 - 0) + (12 - 3) = 9
P1	(3 - 1) = 2
P2	(6 - 2) + (14 - 9) + (20 - 17) = 12
Р3	(9 - 3) + (17 - 12) = 11
	Average Wait Time: $(9+2+12+11)/4 = 8.5$

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

### **Multiple-Level Queues Scheduling**

Multiple-level queues are not an independent scheduling algorithm. They make use of other existing algorithms to group and schedule jobs with common characteristics.

- Multiple queues are maintained for processes with common characteristics.
- Each queue can have its own scheduling algorithms.
- Priorities are assigned to each queue.

For example, CPU-bound jobs can be scheduled in one queue and all I/O-bound jobs in another queue. The Process Scheduler then alternately selects jobs from each queue and assigns them to the CPU based on the algorithm assigned to the queue.

## **Context Switch**

- A context switch is the mechanism to store and restore the state or context of a CPU in Process Control block so that a process execution can be resumed from the same point at a later time. Using this technique a context switcher enables multiple processes to share a single CPU. Context switching is an essential part of a multitasking operating system features.
- When the scheduler switches the CPU from executing one process to execute another, the context switcher saves the content of all processor registers for the process being removed from the CPU, in its process descriptor. The context of a process is represented in the process control block of a process.
- Context switch time is pure overhead. Context switching can significantly affect performance as modern computers have a lot of general and status registers to be saved. Content switching times are highly dependent on hardware support. Context switch requires (n + m) bxK time units to save the state of the processor with n general registers, assuming b are the store operations are required to save n and m registers of two process control blocks and each store instruction requires K time units.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

Some hardware systems employ two or more sets of processor registers to reduce the amount of context switching time. When the process is switched, the following information is stored.

- Program Counter
- Scheduling Information
- Base and limit register value
- Currently used register
- Changed State
- I/O State
- Accounting

## **CONCURRENT AND PROCESSES**

#### **<u>Co-operation of Process</u>**

Processes executing concurrently in the operating system may be either independent processes or cooperating processes. A process is cooperating if it can affect or be affected by the other processes executing in the system. Clearly, any process that shares data with other

COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

processes is a cooperating process. There are several reasons for providing an environment that allows process cooperation:

• **Information sharing**. Since several users may be interested in the same piece of information (for instance, a shared file).It must provide an environment to allow concurrent access to such information.

• **Computation speedup**. If we want a particular task to run faster, we must break it into subtasks, each of which will be executing in parallel with the others. Notice that such a speedup can be achieved only if the computer has multiple processing cores.

• **Modularity.** We may want to construct the system in a modular fashion, dividing the system functions into separate processes or threads,

• **Convenience.** Even an individual user may work on many tasks at the same time. For instance, a user may be editing, listening to music, and compiling in parallel.

Cooperating processes require an inter-process communication (IPC) mechanism that will allow them to exchange data and information. There are two fundamental models of inter-process communication: shared memory and message passing. In the shared-memory model, a region of memory that is shared by cooperating processes is established. Processes can then exchange information by reading and writing data to the shared region. In the message-passing model, communication takes place by means of messages exchanged between the cooperating processes.

## **CRITICAL SECTION PROBLEM**

Consider a system consisting of n processes  $\{P0, P1, ..., Pn-1\}$ . Each process has a segment of code, called a critical section, in which the process may be changing common variables, updating a table, writing a file, and so on. The important feature of the system is that, when one process is executing in its critical section, no other process is allowed to execute in its critical section. That is, no two processes are executing in their critical sections at the same time.

The critical-section problem is to design a protocol that the processes can use to cooperate. Each process must request permission to enter its critical section. The section of code implementing this request is the entry section. The critical section may be followed by an exit section. The remaining code is the remainder section.

A solution to the critical-section problem must satisfy the following three requirements:

COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

1. **Mutual exclusion**. If process Pi is executing in its critical section, then no other processes can be executing in their critical sections.

2. **Progress**. If no process is executing in its critical section and some processes wish to enter their critical sections, then only those processes that are not executing in their remainder sections can participate in deciding which will enter its critical section next, and this selection cannot be postponed indefinitely.

3. **Bounded waiting**. There exists a bound, or limit, on the number of times that other processes are allowed to enter their critical sections after a process has made a request to enter its critical section and before that request is granted.

Two general approaches are used to handle critical sections in operating systems: preemptive kernels and non-preemptive kernels. A preemptive kernel allows a process to be preempted while it is running in kernel mode. A non-preemptive kernel does not allow a process running in kernel mode to be preempted; a kernel-mode process will run until it exits kernel mode, blocks, or voluntarily yields control of the CPU.

# **SEMAPHORE**

Mutex locks, as we mentioned earlier, are generally considered the simplest of synchronization tools. In this section, we examine a more robust tool that can behave similarly to a mutex lock but can also provide more sophisticated ways for processes to synchronize their activities. A semaphore S is an integer variable that, apart from initialization, is accessed only through two standard atomic operations: wait() and signal(). The wait() operation was originally termed P (from the Dutch proberen, "to test"); signal() was originally called V (from verhogen, "to increment"). The definition of wait() is as follows:

```
wait(S) {
while (S <= 0)
; // busy wait
S--;
}
The definition of signal() is as follows:
signal(S) {</pre>
```

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

S++;

}

All modifications to the integer value of the semaphore in the wait () and signal () operations must be executed indivisibly. That is, when one process modifies the semaphore value, no other process can simultaneously modify that same semaphore value. In addition, in the case of wait(S), the testing of the integer value of S (S  $\leq$  0), as well as its possible modification (S--), must be executed without interruption.

## Semaphore Usage

Operating systems often distinguish between **counting and binary semaphores**. The value of a **counting semaphore** can range over an unrestricted domain. The value of a binary semaphore can range only between 0 and 1. Thus, **binary semaphores** behave similarly to mutex locks. Counting semaphores can be used to control access to a given resource consisting of a finite number of instances. The semaphore is initialized to the number of resources available. Each process that wishes to use a resource performs a wait() operation on the semaphore (thereby decrementing the count). When a process releases a resource, it performs a signal () operation (incrementing the count). When the count for the semaphore goes to 0, all resources are being used. After that, processes that wish to use a resource will block until the count becomes greater than 0.

## **Deadlock and Starvation**

The implementation of a semaphore with a waiting queue may result in a situation where two or more processes are waiting indefinitely for an event that can be caused only by one of the waiting processes. The event in question is the execution of a signal() operation. When such a state is reached, these processes are said to be deadlocked. To illustrate this, consider a system consisting of two processes, P0 and P1, each accessing two semaphores, S and Q, set to the value 1: P0 P1

```
wait(S); wait(Q);
wait(Q); wait(S);
...
```

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

signal(S); signal(Q);

signal(Q); signal(S);

Suppose that P0 executes wait(S) and then P1 executes wait(Q).When P0 executes wait(Q), it must wait until P1 executes signal(Q). Similarly, when P1 executes wait(S), it must wait until P0 executes signal(S). Since these signal() operations cannot be executed, P0 and P1 are deadlocked. We say that a set of processes is in a deadlocked state when every process in the set is waiting for an event that can be caused only by another process in the set.

The events with which we are mainly concerned here are resource acquisition and release Another problem related to deadlocks is indefinite blocking or starvation, a situation in which processes wait indefinitely within the semaphore. Indefinite blocking may occur if we remove processes from the list associated with a semaphore in LIFO (last-in, first-out) order.

# METHODS OF INTER-PROCESS COMMUNICATION (IPC)

Inter-process communication using shared memory requires communicating processes to establish a region of shared memory. Typically, a shared-memory region resides in the address space of the process creating the shared-memory segment. Other processes that wish to communicate using this shared-memory segment must attach it to their address space. Shared memory requires that two or more processes agree to remove this restriction. They can then exchange information by reading and writing data in the shared areas. The form of the data and the location are determined by these processes and are not under the operating system's control.

The processes are also responsible for ensuring that they are not writing to the same location simultaneously. Two types of buffers can be used. The unbounded buffer places no practical limit on the size of the buffer. The consumer may have to wait for new items, but the producer can always produce new items. The bounded buffer assumes a fixed buffer size. In this case, the consumer must wait if the buffer is empty, and the producer must wait if the buffer is full.

## Message-Passing Systems

Message passing provides a mechanism to allow processes to communicate and to synchronize their actions without sharing the same address space. It is particularly useful in a

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

distributed environment, where the communicating processes may reside on different computers connected by a network. For example, an Internet chat program could be designed so that chat participants communicate with one another by exchanging messages. A message-passing facility provides at least two operations:

# send(message) receive(message)

Messages sent by a process can be either fixed or variable in size. If only fixed-sized messages can be sent, the system-level implementation is straightforward. This restriction, however, makes the task of programming more difficult. Conversely, variable-sized messages require a more complex system common kind of tradeoff seen throughout operating-system design. If processes P and Q want to communicate, they must send messages to and receive messages from each other: a communication link must exist between them. This link can be implemented in a variety of ways. We are concerned here not with the link's physical implementation (such as shared memory, hardware bus, or network, but rather with its logical implementation. Here are several methods for logically implementing a link and the send()/receive() operations:

- Direct or indirect communication
- Synchronous or asynchronous communication
- Automatic or explicit buffering

# <u>Naming</u>

Processes that want to communicate must have a way to refer to each other. They can use either direct or indirect communication. Under direct communication, each process that wants to communicate must explicitly name the recipient or sender of the communication. In this scheme, the send() and receive() primitives are defined as:

• send(P, message)—Send a message to process P.

• receive(Q, message)—Receive a message from process Q.

A communication link in this scheme has the following properties:

• A link is established automatically between every pair of processes that want to communicate. The processes need to know only each other's identity to communicate.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- A link is associated with exactly two processes.
- Between each pair of processes, there exists exactly one link.

This scheme exhibits symmetry in addressing; that is, both the sender process and the receiver process must name the other to communicate. A variant of this scheme employs asymmetry in addressing. Here, only the sender names the recipient; the recipient is not required to name the sender. In this scheme, the send () and receive () primitives are defined as follows:

- send (P, message)—Send a message to process P.
- receive (id, message)—Receive a message from any process. The variable id is set to the name of the process with which communication has taken place.

The disadvantage in both of these schemes (symmetric and asymmetric) is the limited modularity of the resulting process definitions. Changing the identifier of a process may necessitate examining all other process definitions. All references to the old identifier must be found, so that they can be modified to the new identifier. In general, any such hard-coding techniques, where identifiers must be explicitly stated, are less desirable than techniques involving indirection.

With indirect communication, the messages are sent to and received from mailboxes, or ports. A mailbox can be viewed abstractly as an object into which messages can be placed by processes and from which messages can be removed. Each mailbox has a unique identification. For example, POSIX message queues use an integer value to identify a mailbox. A process can communicate with another process via a number of different mailboxes, but two processes can communicate only if they have a shared mailbox. The send () and receive () primitives are defined as follows:

• send (A, message)—Send a message to mailbox A.

• receive (A, message)—Receive a message from mailbox A.

In this scheme, a communication link has the following properties:

• A link is established between a pair of processes only if both members of the pair have a shared mailbox.

• A link may be associated with more than two processes.

COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

• Between each pair of communicating processes, a number of different links may exist, with each link corresponding to one mailbox.

Now suppose that processes P1, P2, and P3 all share mailbox A. Process P1 sends a message to A, while both P2 and P3 execute a receive() from A. Which process will receive the message sent by P1? The answer depends on which of the following methods we choose:

• Allow a link to be associated with two processes at most.

• Allow at most one process at a time to execute a receive () operation.

• Allow the system to select arbitrarily which process will receive the message (that is, either P2 or P3, but not both, will receive the message).

The system may define an algorithm for selecting which process will receive the message (for example, round robin, where processes take turns receiving messages). The system may identify the receiver to the sender. A mailbox may be owned either by a process or by the operating system.

If the mailbox is owned by a process (that is, the mailbox is part of the address space of the process), then we distinguish between the owner (which can only receive messages through this mailbox) and the user (which can only send messages to the mailbox). Since each mailbox has a unique owner, there can be no confusion about which process should receive a message sent to this mailbox. When a process that owns a mailbox terminates, the mailbox disappears.

Any process that subsequently sends a message to this mailbox must be notified that the mailbox no longer exists. In contrast, a mailbox that is owned by the operating system has an existence of its own. It is independent and is not attached to any particular process. The operating system then must provide a mechanism that allows a process to do the following:

- Create a new mailbox.
- Send and receive messages through the mailbox.
- Delete a mailbox.

The process that creates a new mailbox is that mailbox's owner by default. Initially, the owner is the only process that can receive messages through this mailbox. However, the ownership and receiving privilege may be passed to other processes through appropriate system calls. Of course, this provision could result in multiple receivers for each mailbox.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

## **Synchronization**

Communication between processes takes place through calls to send() and receive() primitives. There are different design options for implementing each primitive. Message passing may be either blocking or non blocking— also known as synchronous and asynchronous. (Throughout this text, you will encounter the concepts of synchronous and asynchronous behavior in relation to various operating-system algorithms.)

• Blocking send. The sending process is blocked until the message is received by the receiving process or by the mailbox.

• Non-blocking send. The sending process sends the message and resumes operation.

- Blocking receive. The receiver blocks until a message is available.
- Non-blocking receive. The receiver retrieves either a valid message or a null.

Different combinations of send () and receive () are possible. When both send () and receive () are blocking, we have a rendezvous between the sender and the receiver. The solution to the producer–consumer problem becomes trivial when we use blocking send () and receive () statements. The producer merely invokes the blocking send () call and waits until the message is delivered to either the receiver or the mailbox. Likewise, when the consumer invokes receive (), it blocks until a message is available.

## **Buffering**

Whether communication is direct or indirect, messages exchanged by communicating processes reside in a temporary queue. Basically, such queues can be implemented in three ways: • Zero capacity. The queue has a maximum length of zero; thus, the link cannot have any

messages waiting in it. In this case, the sender must block until the recipient receives the message.

• Bounded capacity. The queue has finite length n; thus, at most n messages can reside in it. If the queue is not full when a new message is sent, the message is placed in the queue (either the message is copied or a pointer to the message is kept), and the sender can continue execution without waiting. The link's capacity is finite, however. If the link is full, the sender must block until space is available in the queue.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

• Unbounded capacity. The queue's length is potentially infinite; thus, any number of messages can wait in it. The sender never blocks.

The zero-capacity case is sometimes referred to as a message system with no buffering. The other cases are referred to as systems with automatic buffering.

# **DEADLOCK**

Under the normal mode of operation, a process may utilize a resource in only the following sequence:

1. Request. The process requests the resource. If the request cannot be granted immediately (for example, if the resource is being used by another process), then the requesting process must wait until it can acquire the resource.

2. Use. The process can operate on the resource (for example, if the resource is a printer, the process can print on the printer).

3. Release. The process releases the resource.

- For each use of a kernel-managed resource by a process or thread, the operating system checks to make sure that the process has requested and has been allocated the resource. A system table records whether each resource is free or allocated. For each resource that is allocated, the table also records the process to which it is allocated. If a process requests a resource that is currently allocated to another process, it can be added to a queue of processes waiting for this resource.
- A set of processes is in a deadlocked state when every process in the set is waiting for an event that can be caused only by another process in the set. The events with which we are mainly concerned here are resource acquisition and release. The resources may be either physical resources (for example, printers, tape drives, memory space, and CPU cycles) or logical resources (for example, semaphores, mutex locks, and files).

#### **Deadlock Prevention**

## **Mutual Exclusion**

> The mutual exclusion condition must hold. That is, at least one resource must be non-sharable. Sharable resources, in contrast, do not require mutually exclusive

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

access and thus cannot be involved in a deadlock. Read-only files are a good example of a sharable resource. If several processes attempt to open a read-only file at the same time, they can be granted simultaneous access to the file.

A process never needs to wait for a sharable resource. In general, however, we cannot prevent deadlocks by denying the mutual-exclusion condition, because some resources are intrinsically non-sharable. For example, a mutex lock cannot be simultaneously shared by several processes.

## Hold and Wait

- To ensure that the hold-and-wait condition never occurs in the system, we must guarantee that, whenever a process requests a resource, it does not hold any other resources.
- One protocol that we can use requires each process to request and be allocated all its resources before it begins execution. We can implement this provision by requiring that system calls requesting resources for a process precede all other system calls. An alternative protocol allows a process to request resources only when it has none.
- A process may request some resources and use them. Before it can request any additional resources, it must release all the resources that it is currently allocated.
- Both these protocols have two main disadvantages. First, resource utilization may be low, since resources may be allocated but unused for a long period. In the example given, for instance, we can release the DVD drive and disk file, and then request the disk file and printer, only if we can be sure that our data will remain on the disk file. Otherwise, we must request all resources at the beginning for both protocols.
- Second, starvation is possible. A process that needs several popular resources may have to wait indefinitely, because at least one of the resources that it needs is always allocated to some other process.

#### No Preemption

The third necessary condition for deadlocks is that there be no preemption of resources that have already been allocated. To ensure that this condition does not hold, we can use the following protocol.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- If a process is holding some resources and requests another resource that cannot be immediately allocated to it (that is, the process must wait), then all resources the process is currently holding are preempted. In other words, these resources are implicitly released. The preempted resources are added to the list of resources for which the process is waiting.
- The process will be restarted only when it can regain its old resources, as well as the new ones that it is requesting. Alternatively, if a process requests some resources, we first check whether they are available. If they are, we allocate them. If they are not, we check whether they are allocated to some other process that is waiting for additional resources. If so, we preempt the desired resources from the waiting process and allocate them to the requesting process. If the resources are neither available nor held by a waiting process, the requesting process must wait.
- While it is waiting, some of its resources may be preempted, but only if another process requests them. A process can be restarted only when it is allocated the new resources it is requesting and recovers any resources that were preempted while it was waiting.

# <u>Circular Wait</u>

- The fourth and final condition for deadlocks is the circular-wait condition. One way to ensure that this condition never holds is to impose a total ordering of all resource types and to require that each process requests resources in an increasing order of enumeration.
- ➤ To illustrate, we let R = {R1, R2, ..., Rm} be the set of resource types. We assign to each resource type a unique integer number, which allows us to compare two resources and to determine whether one precedes another in our ordering. Formally, we define a one-to-one function F: R→N, where N is the set of natural numbers. For example, if the set of resource types R includes tape drives, disk drives, and printers, then the function F might be defined as follows:

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- ➤ We can now consider the following protocol to prevent deadlocks: Each process can request resources only in an increasing order of enumeration. That is, a process can initially request any number of instances of a resource type —say, Ri . After that, the process can request instances of resource type Rj if and only if F(Rj ) > F(Ri ). For example, using the function defined previously, a process that wants to use the tape drive and printer at the same time must first request the tape drive and then request the printer.
- Alternatively, we can require that a process requesting an instance of resource type Rj must have released any resources Ri such that  $F(Ri ) \ge F(Rj )$ . Note also that if several instances of the same resource type are needed, a single request for all of them must be issued. If these two protocols are used, then the circular-wait condition cannot hold. We can demonstrate this fact by assuming that a circular wait exists (proof by contradiction). Let the set of processes involved in the circular wait be {P0, P1, ..., Pn}, where Pi is waiting for a resource Ri , which is held by process Pi+1. (Modulo arithmetic is used on the indexes, so that Pn is waiting for a resource Ri +1, we must have F(Ri ) < F(Ri+1) for all i. But this condition means that F(R0) < F(R1) < ... < F(Rn) < F(R0). By transitivity, F(R0) < F(R0), which is impossible. Therefore, there can be no circular wait.

## **Deadlock Avoidance:**

- For avoiding deadlocks, it is to require additional information about how resources are to be requested. For example, in a system with one tape drive and one printer, the system might need to know that process P will request first the tape drive and then the printer before releasing both resources, whereas process Q will request first the printer and then the tape drive.
- With this knowledge of the complete sequence of requests and releases for each process, the system can decide for each request whether or not the process should wait in order to avoid a possible future deadlock. Each request requires that in making this decision the system consider the resources currently available, the resources currently allocated to each process, and the future requests and releases of each process.

COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

The various algorithms that use this approach differ in the amount and type of information required. The simplest and most useful model requires that each process declare the maximum number of resources of each type that it may need.

## Safe State:

- A state is safe if the system can allocate resources to each process in some order and still avoid a deadlock. More formally, a system is in a safe state only if there exists a safe sequence.
- A sequence of processes <P1, P2, ..., Pn> is a safe sequence for the current allocation state if, for each Pi, the resource requests that Pi can still make can be satisfied by the currently available resources plus the resources held by all Pj, with j < i. In this situation, if the resources that Pi needs are not immediately available, then Pi can wait until all Pj have finished. When they have finished, Pi can obtain all of its needed resources, complete its designated task, return its allocated resources, and terminate. When Pi terminates, Pi+l can obtain its needed resources, and so on. If no such sequence exists, then the system state is said to be unsafe. A safe state is not a deadlocked state. Conversely, a deadlocked state is an unsafe state.</p>

 $\triangleright$ 

# **Resource-Allocation-Graph Algorithm**

- If we have a resource-allocation system with only one instance of each resource type, we can use a variant of the resource-allocation graph defined for deadlock avoidance. In addition to the request and assignment edges already described, we introduce a new type of edge, called a claim edge.
- A claim edge Pi ~ Rj indicates that process Pi may request resource Rj at some time in the future. This edge resembles a request edge in direction but is represented in the graph by a dashed line. When process Pi requests resource R1, the claim edge P; -+ R1 is converted to a request edge. Similarly, when a resource R1 is released by P;, the assignment edge Rj -+ P; is reconverted to a claim edge P; -+ Rj.
- We note that the resources must be claimed a priori in the system. That is, before process P; starts executing, all its claim edges must already appear in the resource-allocation

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

graph. We can relax this condition by allowing a claim edge P; -+ R1 to be added to the graph only if all the edges associated with process P; are claim edges. Now suppose that process P; requests resource Rj. The request can be granted only if converting the request edge P; -+ Rj to an assignment edge R1 -+ P; does not result in the formation of a cycle in the resource-allocation graph. We check for safety by using a cycle-detection algorithm.

An algorithm for detecting a cycle in this graph requires an order of n2 operations, where n is the number of processes in the system. If no cycle exists, then the allocation of the resource will leave the system in a safe state. If a cycle is found, then the allocation will put the system in an unsafe state. In that case, process P; will have to wait for its requests to be satisfied. To illustrate this algorithm, we consider the following resource-allocation graph.

Suppose that P2 requests R2. Although R2 is currently free, we cannot allocate it to P2, since this action will create a cycle in the graph .A cycle, as mentioned, indicates that the system is in an unsafe state. If P1 requests R2, and P2 requests R1, then a deadlock will occur.

# **Banker's algorithm:**

The resource-allocation-graph algorithm is not applicable to a resource allocation system with multiple instances of each resource type. The Banker's algorithm is less efficient than the resource-allocation graph scheme. This algorithm is commonly known as the banker's algorithm. When a new process enters the system, it must declare the maximum

COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

number of instances of each resource type that it may need. This nun1.ber may not exceed the total number of resources in the system.

When a user requests a set of resources, the system must determine whether the allocation of these resources will leave the system in a safe state. If it will, the resources are allocated; otherwise, the process must wait until some other process releases enough resources. Several data structures must be maintained to implement the banker's algorithm. These data structures encode the state of the resource-allocation system. We need the following data structures, where n is the number of processes in the system and m is the number of resource types:

**Available:** A vector of length m indicates the number of available resources of each type. If Available[j] equals k, then k instances of resource type Ri are available.

**Max:** An n x m matrix defines the maximum demand of each process. If Max[i] [j] equals k, then process P; may request at most k instances of resource type Ri.

Allocation: An 11 x m matrix defines the number of resources of each type currently allocated to each process. If Allocation[i][j] equals lc, then process P; is currently allocated lc instances of resource type Rj.

**Need:** An n x m matrix indicates the remaining resource need of each process. If Need[i][j] equals k, then process P; may need k more instances of resource type Ri to complete its task. Note that Need[i][j] equals Max[i][j] - Allocation [i][j].

These data structures vary over time in both size and value. To simplify the presentation of the banker's algorithm, we next establish some notation. Let X andY be vectors of length 11. We say that X::= Y if and only if X[i] ::= Y[i] for all i = 1, 2, ..., n. For example, if X = (1,7,3,2) and Y = (0,3,2,1), then Y ::=X. In addition, Y < X if Y ::=X and Y# X. We can treat each row in the matrices Allocation and Need as vectors and refer to them as Allocation; and Need;. The vector Allocation; specifies the resources currently allocated to process P;; the vector Need; specifies the additional resources that process P; may still request to complete its task.

## Safety Algorithm

 Let Work and Finish be vectors of length m and n, respectively. Initialize Work= Available and Finish[i] =false for i = 0, 1, ..., n - 1.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

- 2. Find an index i such that both
  - a. Finish[i] == false
  - b. Need<sub>i</sub> Work. If no such i exists, go to step 4.
- 3. Work = Work + Allocation; Finish[i] = true. Go to step 2.
- 4. If Finish[i] ==true for all i, then the system is in a safe state.

# **Resource-Request Algorithm**

Let Request; be the request vector for process P;. If Request; [j] == k, then process P; wants k instances of resource type Rj. When a request for resources is made by process P;, the following actions are taken:

- 1. If Request; <= Need; go to step 2. Otherwise, raise an error condition, since the process has exceeded its maximum claim.
- If Request< = Available, go to step 3. Otherwise, P; must wait, since the resources are not available.
- 3. Have the system pretend to have allocated the requested resources to process P; by modifyil1.g the state as follows:

Available= Available- Request<sub>i</sub>

# <u>Deadlock</u>

Allocation; =Allocation; +Request<sub>i</sub>

Need; =Need<sub>i</sub>- Request<sub>i</sub>

If the resulting resource-allocation state is safe, the transaction is completed, and process P; is allocated its resources. However, if the new state is unsafe, then P; must wait for Request<sub>i</sub>, and the old resource-allocation state is restored.

# **Deadlock Detection**

If a system does not employ either a deadlock-prevention or a deadlock avoidance algorithm, then a deadlock situation may occur. In this environment, the system may provide:

• An algorithm that examines the state of the system to determine whether a deadlock has occurred

• An algorithm to recover from the deadlock

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

## Single Instance of Each Resource Type

If all resources have only a single instance, then we can define a deadlock detection algorithm that uses a variant of the resource-allocation graph, called a wait-for graph. We obtain this graph from the resource-allocation graph by removing the resource nodes and collapsing the appropriate edges.

More precisely, an edge from Pi to Pj in a wait-for graph implies that process Pi is waiting for process Pj to release a resource that Pi needs.

An edge  $Pi \rightarrow Pj$  exists in a wait-for graph if and only if the corresponding resource allocation graph contains two edges  $Pi \rightarrow Rq$  and  $Rq \rightarrow Pj$  for some resource Rq. In Figure, we present a resource-allocation graph and the corresponding wait-for graph. As before, a deadlock exists in the system if and only if the wait-for graph contains a cycle.

To detect deadlocks, the system needs to maintain the wait for graph and periodically invoke an algorithm that searches for a cycle in the graph. An algorithm to detect a cycle in a graph requires an order of n2 operations, where n is the number of vertices in the graph.

## Several Instances of a Resource Type

The wait-for graph scheme is not applicable to a resource-allocation system with multiple instances of each resource type. We turn now to a deadlock detection algorithm that is applicable

COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

to such a system. The algorithm employs several time-varying data structures that are similar to those used in the banker's algorithm

• Available. A vector of length m indicates the number of available resources of each type.

• Allocation. An  $n \times m$  matrix defines the number of resources of each type currently allocated to each process.

• Request. An  $n \times m$  matrix indicates the current request of each process. If Request[i][j] equals k, then process Pi is requesting k more instances of resource type Rj. To simplify notation, we again treat the rows in the matrices Allocation and Request as vectors; we refer to them as Allocationi and Requesti . The detection algorithm described here simply investigates every possible allocation sequence for the processes that remain to be completed.

1. Let Work and Finish be vectors of length m and n, respectively. Initialize Work = Available.

For i = 0, 1, ..., n–1, if Allocationi \_= 0, then Finish[i] = false. Otherwise, Finish[i] = true.

2. Find an index i such that both

a. Finish[i] == false

b. Requesti ≤Work

If no such i exists, go to step 4.

3. Work = Work + Allocationi

Finish[i] = true

Go to step 2.

4. If Finish[i] == false for some i,  $0 \le i < n$ , then the system is in a deadlocked state. Moreover, if Finish[i] == false, then process Pi is deadlocked. This algorithm requires an order of m × n2 operations to detect whether the system is in a deadlocked state. You may wonder why we reclaim the resources of process Pi (in step 3) as soon as we determine that Requesti  $\le$  Work (in step 2b). We know that Pi is currently not involved in a deadlock (since Requesti  $\le$  Work). Thus, we take an optimistic attitude and assume that Pi will require no more resources to complete its task; it will thus soon return all currently allocated resources to the system. If our assumption is incorrect, a deadlock may occur later. That deadlock will be detected the next time the deadlock-detection algorithm is invoked.

COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

To illustrate this algorithm, we consider a system with five processes P0 through P4 and three resource types A, B, and C. Resource type A has seven instances, resource type B has two instances, and resource type C has six instances. Suppose that, at time T0, we have the following resource-allocation state:

	Allocation	Request	Available	
	A B C	A B C	A B C	
P0	010	000	000	
P1	200	202		
P2	303	000		
Р3	211	100		
P4	002	002		

We claim that the system is not in a deadlocked state. Indeed, if we execute our algorithm, we will find that the sequence <P0, P2, P3, P1, P4> results in Finish[i] == true for all i. Suppose now that process P2 makes one additional request for an instance of type C. The Request matrix is modified as follows:

	Request	
	A B C	
P0	000	
P1	202	
P2	001	
Р3	100	
P4	002	

We claim that the system is now deadlocked. Although we can reclaim the resources held by process P0, the number of available resources is not sufficient to fulfill the requests of the other processes. Thus, a deadlock exists, consisting of processes P1, P2, P3, and P4.

## **Recovery from Deadlock**

When a detection algorithm determines that a deadlock exists, several alternatives are available. One possibility is to inform the operator that a deadlock has occurred and to let the

COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

operator deal with the deadlock manually. Another possibility is to let the system recover from the deadlock automatically. There are two options for breaking a deadlock.

## **Process Termination**

To eliminate deadlocks by aborting a process, we use one of two methods. In both methods, the system reclaims all resources allocated to the terminated processes.

• Abort all deadlocked processes. This method clearly will break the deadlock cycle, but at great expense. The deadlocked processes may have computed for a long time, and the results of these partial computations must be discarded and probably will have to be recomputed later.

• Abort one process at a time until the deadlock cycle is eliminated. This method incurs considerable overhead, since after each process is aborted, a deadlock-detection algorithm must be invoked to determine whether any processes are still deadlocked.

Aborting a process may not be easy. If the process was in the midst of updating a file, terminating it will leave that file in an incorrect state. Similarly, if the process was in the midst of printing data on a printer, the system must reset the printer to a correct state before printing the next job.

# **Resource Preemption**

To eliminate deadlocks using resource preemption, we successively preempt some resources from processes and give these resources to other processes until the deadlock cycle is broken. If preemption is required to deal with deadlocks, then three issues need to be addressed:

1. Selecting a victim. Which resources and which processes are to be preempted? As in process termination, we must determine the order of preemption to minimize cost. Cost factors may include such parameters as the number of resources a deadlocked process is holding and the amount of time the process has thus far consumed.

2. Rollback. If we preempt a resource from a process, what should be done with that process? Clearly, it cannot continue with its normal execution; it is missing some needed resource. We must roll back the process to some safe state and restart it from that state. Since, in general, it is difficult to determine what a safe state is, the simplest solution is a total rollback: abort the process and then restart it. Although it is more effective to roll back the process only as far as

COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - II BATCH: 2016 – 2019

necessary to break the deadlock, this method requires the system to keep more information about the state of all running processes.

3. Starvation. How do we ensure that starvation will not occur? That is, how can we guarantee that resources will not always be preempted from the same process?

In a system where victim selection is based primarily on cost factors, it may happen that the same process is always picked as a victim. As a result, this process never completes its designated task, a starvation situation any practical system must address. Clearly, we must ensure that a process can be picked as a victim only a (small) finite number of times. The most common solution is to include the number of rollbacks in the cost factor.

## POSSIBLE QUESTIONS UNIT – II PART – A (20 MARKS) (Q.NO 1 TO 20 Online Examinations)

## PART – B (2 MARKS)

- 1. Define internal commands in Unix.
- 2. What is External commands in Linux.
- 3. What do you mean by partition in OS?
- 4. Define Fork command.
- 5. Define Wait commands

## PART – C (6 MARKS)

- 1. Discuss in detail the System Processes.
- 2. Explain the external and internal commands.
- 3. Explain the creation of partitions in OS.
- 4. Explain the processes and its creation phases.
- 5. Discuss the commands of fork, exec and wait.

**Coimbatore – 641 021.**

# <u>UNIT – III</u> SYLLABUS

**User Management and the File System** Types of Users, Creating users, Granting rights User management commands, File quota and various file systems available, File System Management and Layout, File permissions, Login process, Managing Disk Quotas, Links (hard links, symbolic links)

- The operating system, executing in kernel mode, is given unrestricted access to both operating-system memory and users' memory. This provision allows the operating system to load users' programs into users' memory, to dump out those programs in case of errors, to access and modify parameters of system calls, to perform I/O to and from user memory, and to provide many other services.
- Consider, for example, that an operating system for a multiprocessing system must execute context switches, storing the state of one process from the registers into main memory before loading the next process's context from main memory into the registers. This scheme allows the operating system to change the value of the registers but prevents user programs from changing the registers' contents.

### Address Binding

- Memory management is the functionality of an operating system which handles or manages primary memory. Memory management keeps track of each and every memory location either it is allocated to some process or it is free. It checks how much memory is to be allocated to processes. It decides which process will get memory at what time. It tracks whenever some memory gets freed or unallocated and correspondingly it updates the status.
- Memory management provides protection by using two registers, a base register and a limit register. The base register holds the smallest legal physical memory address and the limit register specifies the size of the range. For example, if the base register holds 300000 and the limit register is 1209000, then the program can legally access all addresses from 300000 through 411999.

Instructions and data to memory addresses can be done in following ways

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- Compile time -- When it is known at compile time where the process will reside, compile time binding is used to generate the absolute code.
- Load time -- When it is not known at compile time where the process will reside in memory, then the compiler generates re-locatable code.
- Execution time -- If the process can be moved during its execution from one memory segment to another, then binding must be delayed to be done at run time

### **Dynamic Loading**

- In dynamic loading, a routine of a program is not loaded until it is called by the program. All routines are kept on disk in a re-locatable load format. The main program is loaded into memory and is executed. Other routines methods or modules are loaded on request. Dynamic loading makes better memory space utilization and unused routines are never loaded.
- The advantage of dynamic loading is that a routine is loaded only when it is needed. This method is particularly useful when large amounts of code are needed to handle infrequently occurring cases, such as error routines. In this case, although the total program size may be large, the portion that is used (and hence loaded) may be much smaller.
- Dynamic loading does not require special support from the operating system. It is the
  responsibility of the users to design their programs to take advantage of such a method.
  Operating systems may help the programmer, however, by providing library routines to
  implement dynamic loading.

#### **Dynamic Linking**

• Linking is the process of collecting and combining various modules of code and data into a executable file that can be loaded into memory and executed. Operating system can link system level libraries to a program. When it combines the libraries at load time, the linking is called static linking and when this linking is done at the time of execution, it is called as dynamic linking.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- In static linking, libraries linked at compile time, so program code size becomes bigger whereas in dynamic linking libraries linked at execution time so program code size remains smaller.
- Unlike dynamic loading, dynamic linking and shared libraries generally require help from the operating system. If the processes in memory are protected from one another, then the operating system is the only entity that can check to see whether the needed routine is in another process's memory space or that can allow multiple processes to access the same memory addresses.

#### PHYSICAL AND VIRTUAL ADDRESS SPACE

#### Logical (Virtual) versus Physical Address Space

An address generated by the CPU is a logical address whereas address actually available on memory unit is a physical address. Logical address is also known a Virtual address. Virtual and physical addresses are the same in compile-time and load-time address-binding schemes. Virtual and physical addresses differ in execution-time address-binding scheme.

The set of all logical addresses generated by a program is referred to as a logical address space. The set of all physical addresses corresponding to these logical addresses is referred to as a physical address space.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

The run-time mapping from virtual to physical address is done by the memory management unit (MMU) which is a hardware device.

MMU uses following mechanism to convert virtual address to physical address.

- The value in the base register is added to every address generated by a user process which is treated as offset at the time it is sent to memory. For example, if the base register value is 10000, then an attempt by the user to use address location 100 will be dynamically reallocated to location 10100.
- The user program deals with virtual addresses; it never sees the real physical addresses.

## **MEMORY ALLOCATION STRATEGIES**

### **Contiguous Memory Allocation**

- The main memory must accommodate both the operating system and the various user processes. We therefore need to allocate main memory in the most efficient way possible. The memory is usually divided into two partitions: one for the resident operating system and one for the user processes.
- We can place the operating system in either low memory or high memory. The major factor affecting this decision is the location of the interrupt vector. Since the interrupt vector is often in low memory, programmers usually place the operating system in low memory as well.
- We usually want several user processes to reside in memory at the same time. We therefore need to consider how to allocate available memory to the processes that are in the input queue waiting to be brought into memory. In contiguous memory allocation, each process is contained in a single section of memory that is contiguous to the section containing the next process.

### **Memory Protection**

• Before discussing memory allocation further, we must discuss the issue of memory protection. If we have a system with a relocation register, together with a limit, we accomplish our goal. The relocation register contains the value of the smallest physical

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

address; the limit register contains the range of logical addresses (for example, relocation = 100040 and limit = 74600).

• Each logical address must fall within the range specified by the limit register. The MMU maps the logical address dynamically by adding the value in the relocation register. This mapped address is sent to memory. When the CPU scheduler selects a process for execution, the dispatcher loads the relocation and limit registers with the correct values as part of the context switch. Because every address generated by a CPU is checked against these registers, we can protect both the operating system and the other users' programs and data from being modified by this running process.

### **Memory Allocation**

- One of the simplest methods for allocating memory is to divide memory into several fixedsized **partitions**. Each partition may contain exactly one process. Thus, the degree of multiprogramming is bound by the number of partitions. In this multiple **partition method**, when a partition is free, a process is selected from the input queue and is loaded into the free partition.
- When the process terminates, the partition becomes available for another process. This
  method was originally used by the IBM OS/360 operating system (called MFT) but is no
  longer in use. The method described next is a generalization of the fixed-partition scheme
  (called MVT); it is used primarily in batch environments. Many of the ideas presented here
  are also applicable to a time-sharing environment in which pure segmentation is used for
  memory management.
- In the variable-partition scheme, the operating system keeps a table indicating which parts of memory are available and which are occupied. Initially, all memory is available for user processes and is considered one large block of available memory, a hole. Eventually, as you will see, memory contains a set of holes of various sizes.
- As processes enter the system, they are put into an input queue. The operating system takes into account the memory requirements of each process and the amount of available memory space in determining which processes are allocated memory.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- When a process is allocated space, it is loaded into memory, and it can then compete for CPU time. When a process terminates, it releases its memory, which the operating system may then fill with another process from the input queue.
- In general, the memory blocks available comprise a set of holes of various sizes scattered throughout memory. When a process arrives and needs memory, the system searches the set for a hole that is large enough for this process. If the hole is too large, it is split into two parts. One part is allocated to the arriving process; the other is returned to the set of holes. When a process terminates, it releases its block of memory, which is then placed back in the set of holes.
- If the new hole is adjacent to other holes, these adjacent holes are merged to form one larger hole. At this point, the system may need to check whether there are processes waiting for memory and whether this newly freed and recombined memory could satisfy the demands of any of these waiting processes. This procedure is a particular instance of the general dynamic storage allocation problem, which concerns how to satisfy a request of size n from a list of free holes. There are many solutions to this problem. The first-fit, best-fit, and worst-fit strategies are the ones most commonly used to select a free hole from the set of available holes.

• First fit. Allocate the first hole that is big enough. Searching can start either at the beginning of the set of holes or at the location where the previous first-fit search ended. We can stop searching as soon as we find a free hole that is large enough.

• **Best fit.** Allocate the smallest hole that is big enough. We must search the entire list, unless the list is ordered by size. This strategy produces the smallest leftover hole.

• Worst fit. Allocate the largest hole. Again, we must search the entire list, unless it is sorted by size. This strategy produces the largest leftover hole, which may be more useful than the smaller leftover hole from a best-fit approach.

#### **Fragmentation**

• Both the first-fit and best-fit strategies for memory allocation suffer from **external fragmentation.** As processes are loaded and removed from memory, the free memory space is broken into little pieces. External fragmentation exists when there is enough total memory

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

space to satisfy a request but the available spaces are not contiguous: storage is fragmented into a large number of small holes. This fragmentation problem can be severe. In the worst case, we could have a block of free (or wasted) memory between every two processes. If all these small pieces of memory were in one big free block instead, we might be able to run several more processes.

- Whether we are using the first-fit or best-fit strategy can affect the amount of fragmentation. (First fit is better for some systems, whereas best fit is better for others.) Another factor is which end of a free block is allocated. (Which is the leftover piece—the one on the top or the one on the bottom?) Memory fragmentation can be internal as well as external. Consider a multiple-partition allocation scheme with a hole of 18,464 bytes. Suppose that the next process requests 18,462 bytes. If we allocate exactly the requested block, we are left with a hole of 2 bytes. The overhead to keep track of this hole will be substantially larger than the hole itself.
- The general approach to avoiding this problem is to break the physical memory into fixedsized blocks and allocate memory in units based on block size. With this approach, the memory allocated to a process may be slightly larger than the requested memory. The difference between these two numbers is **internal fragmentation**—unused memory that is internal to a partition.
- One solution to the problem of external fragmentation is compaction. The goal is to shuffle the memory contents so as to place all free memory together in one large block. Compaction is not always possible, however. If relocation is static and is done at assembly or load time, compaction cannot be done. It is possible only if relocation is dynamic and is done at execution time. Another possible solution to the external-fragmentation problem is to permit the logical address space of the processes to be noncontiguous, thus allowing a process to be allocated physical memory wherever such memory is available. Two complementary techniques achieve this solution: segmentation and paging

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

## **PAGING**

- It is a memory-management scheme that permits the physical address space a process to be noncontiguous. Paging avoids external fragmentation and the need for compaction. It also solves the considerable problem of fitting memory chunks of varying sizes onto the backing store; most memory management schemes used before the introduction of paging suffered from this problem. The problem arises because, when some code fragments or data residing in main memory need to be swapped out, space must be framed on the backing store.
- The backing store has the same fragmentation problems discussed in connection with main memory, but access is much slower, so compaction is impossible. Because of its advantages over earlier methods, paging in its various forms is used in most operating systems.

Traditionally, support for paging has been handled by hardware. However, recent designs have implemented paging by closely integrating the hardware and operating system, especially on 64-bit microprocessors.

### **Basic Method**

- The basic method for implementing paging involves breaking physical memory into fixedsized blocks called frames and breaking logical memory into blocks of the same size called pages.
- When a process is to be executed, its pages are loaded into any available memory frames from their source (a file system or the backing store). The backing store is divided into fixed-sized blocks that are of the san1.e size as the memory frames. The hardware support for paging is illustrated in the following figure

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• Every address generated the CPU is divided into two parts: a {p) and a . The page number is used as an index into a page table contains the base address of each page in physical memory. This base address is combined with the page offset to define the physical memory address that is sent to the memory unit. The paging model of memory is shown in the following diagram

• The page size (like the frame size) is defined by the hardware. The size of a page is typically a power of 2, varying between 512 bytes and 16 MB per page, depending on the computer architecture. The selection of a power of 2 as a page size makes the translation of a logical address into a page number and page offset particularly easy.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

page number	page offset
р	d
m-n	п

• If the size of the logical address space is 2m, and a page size is 271 addressing units (bytes or wordst then the high-order m- n bits of a logical address designate the page number, and the n low-order bits designate the page offset. Thus, the logical address is as follows: where p is an index into the page table and d is the displacement within the page. As a concrete (although minuscule) example, consider the memory in the following diagram

- Here, in the logical address, n= 2 and m = 4. Using a page size of 4 bytes and a physical memory of 32 bytes (8 pages), we show how the user's view of memory can be mapped into physical memory. Logical address 0 is page 0, offset 0. Indexing into the page table, we find that page 0 is in frame 5. Thus, logical address 0 maps to physical address 20 [= (5 x 4) + 0]. Logical address 3 (page 0, offset 3) maps to physical address 23 [ = (5 x 4) + 3].
- Logical address 4 is page 1, offset 0; according to the page table, page 1 is mapped to frame
   6. Thus, logical address 4 maps to physical address 24 [ = ( 6 x 4) + O]. Logical address 13 maps to physical address 9. You may have noticed that paging itself is a form of dynamic relocation. Every logical address is bound by the paging hardware to some physical address.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

Using paging is similar to using a table of base (or relocation) registers, one for each frame of memory. When we use a paging scheme, we have no external fragmentation: any free frame can be allocated to a process that needs it. However, we may have some internal fragmentation. Notice that frames are allocated as units.

- If the memory requirements of a process do not happen to coincide with page boundaries, the last frame allocated may not be completely full. For example, if page size is 2,048 bytes, a process of 72,766 bytes will need 35 pages plus 1,086 bytes. It will be allocated 36 frames, resulting in internal fragmentation of 2,048 1,086 = 962 bytes. In the worst case, a process would need 11 pages plus 1 byte. It would be allocated 11 + 1 frames, resulting in internal fragmentation of almost an entire frame. If process size is independent of page size, we expect internal fragmentation to average one-half page per process. This consideration suggests that small page sizes are desirable. Generally, page sizes have grown over time as processes, data sets, and main memory have become larger.
- Today, pages typically are between 4 KB and 8 KB in size and some systems support even larger page sizes. Some CPUs and kernels even support multiple page sizes. For instance, Solaris uses page sizes of 8 KB and 4 MB, depending on the data stored by the pages. Researchers are now developing support for variable on-the-fly page size. Usually, each page-table entry is 4 bytes long, but that size can vary as well. A 32-bit entry can point to one of 232 physical page frames. If frame size is 4 KB, then a system with 4-byte entries can address 244 bytes (or 16 TB) of physical memory. When a process arrives in the system to be executed, its size, expressed in pages, is examined. Each page of the process needs one frame. Thus, if the process requires 11 pages, at least 11 frames must be available in memory.
- If n frames are available, they are allocated to this arriving process. The first page of the process is loaded into one of the allocated frames, and the frame number is put in the page table for this process. The next page is loaded into another frame, its frame number is put into the page table, and so on. An important aspect of paging is the clear separation between the user's view of memory and the actual physical memory. The user program views

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

memory as one single space, containing only this one program. In fact, the user program is scattered throughout physical memory, which also holds other programs.

- The difference between the user's view of memory and the actual physical memory is reconciled by the address-translation hardware. The logical addresses are translated into physical addresses. This mapping is hidden from the user and is controlled by the operating system. Notice that the user process by definition is unable to access memory it does not own.
- It has no way of addressing memory outside of its page table, and the table includes only those pages that the process owns. Since the operating system is managing physical memory, it must be aware of the allocation details of physical memory-which frames are allocated, which frames are available, how many total frames there are, and so on. This information is generally kept in a data structure called a frame the frame-table has one entry for each physical page frame, indicating whether the latter is free or allocated and, if it is allocated, to which page of which process or processes.
- In addition, the operating system must be aware that user processes operate in user space, and all logical addresses must be mapped to produce physical addresses. If a user makes a system call (to do I/0, for example) and provides an address as a parameter (a buffe1~ for instance), that address must be mapped to produce the correct physical address.
- The operating system maintains a copy of the page table for each process, just as it maintains a copy of the instruction counter and register contents. This copy is used to translate logical addresses to physical addresses whenever the operating system must map a logical address to a physical address manually. It is also used by the CPU dispatcher to define the hardware page table when a process is to be allocated the CPU. Paging therefore increases the context-switch time.

#### **STRUCTURE OF PAGE TABLE**

In this section, we explore some of the most common techniques for structuring the page table, including hierarchical paging, hashed page tables, and inverted page tables.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### **Hierarchical Paging**

• Most modern computer systems support a large logical address space (232 to 264). In such an environment, the page table itself becomes excessively large. For example, consider a system with a 32-bit logical address space. If the page size in such a system is 4 KB (212), then a page table may consist of up to 1 million entries (232/212). Assuming that each entry consists of 4 bytes, each process may need up to 4 MB of physical address space for the page table alone. Clearly, we would not want to allocate the page table contiguously in main memory. One simple solution to this problem is to divide the page table into smaller pieces.

• We can accomplish this division in several ways. One way is to use a two-level paging algorithm, in which the page table itself is also paged. For example, consider again the system with a 32-bit logical address space and a page size of 4 KB. A logical address is divided into a page number

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

consisting of 20 bits and a page offset consisting of 12 bits. Because we page the page table, the page number is further divided into a 10-bit page number and a 10-bit page offset. Thus, a logical address is as follows:

Where p1 is an index into the outer page table and p2 is the displacement within the page of the inner page table. The address-translation method for this architecture is shown in Figure. Because address translation works from the outer page table inward, this scheme is also known as a forward-mapped page table.

## Hashed Page Tables

- A common approach for handling address spaces larger than 32 bits is to use a hashed page table, with the hash value being the virtual page number. Each entry in the hash table contains a linked list of elements that hash to the same location (to handle collisions). Each element consists of three fields: (1) the virtual page number, (2) the value of the mapped page frame, and (3) a pointer to the next element in the linked list. The algorithm works as follows:
- The virtual page number in the virtual address is hashed into the hash table. The virtual page number is compared with field 1 in the first element in the linked list. If there is a match, the corresponding page frame (field 2) is used to form the desired physical address. If there is no match, subsequent entries in the linked list are searched for a matching virtual page number.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

#### **Inverted Page Tables**

- Usually, each process has an associated page table. The page table has one entry for each page that the process is using (or one slot for each virtual address, regardless of the latter's validity). This table representation is a natural one, since processes reference pages through the pages' virtual addresses.
- The operating system must then translate this reference into a physical memory address. Since the table is sorted by virtual address, the operating system is able to calculate where in the table the associated physical address entry is located and to use that value directly. One of the drawbacks of this method is that each page table may consist of millions of entries. These tables may consume large amounts of physical memory just to keep track of how other physical memory is being used.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• To solve this problem, we can use an inverted page table. An inverted page table has one entry for each real page (or frame) of memory. Each entry consists of the virtual address of the page stored in that real memory location, with information about the process that owns the page. Thus, only one page table is in the system, and it has only one entry for each page of physical memory.

#### **Shared Pages**

• An advantage of paging is the possibility of sharing common code. This consideration is particularly important in a time-sharing environment. Consider a system that supports 40 users, each of whom executes a text editor. If the text editor consists of 150 KB of code and 50 KB of data space, we need 8,000 KB to support the 40 users. If the code is reentrant code (or pure code), it can be shared, as shown in Figure. Here, we see three processes sharing a three-page editor—each page 50 KB in size (the large page size is used to simplify the figure). Each process has its own data page. Reentrant code is non-self-modifying code: it never changes during execution. Thus, two or more processes can execute the same code at the same time.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- Each process has its own copy of registers and data storage to hold the data for the process's execution. The data for two different processes will, of course, be different. Only one copy of the editor need be kept in physical memory. Each user's page table maps onto the same physical copy of the editor, but data pages are mapped onto different frames. Thus, to support 40 users, we need only one copy of the editor (150 KB), plus 40 copies of the 50 KB of data space per user. The total space required is now 2,150 KB instead of 8,000 KB—a significant savings. Other heavily used programs can also be shared—compilers, window systems, run-time libraries, database systems, and so on. To be sharable, the code must be reentrant. The read-only nature of shared code should not be left to the correctness of the code; the operating system should enforce this property.
- The sharing of memory among processes on a system is similar to the sharing of the address space of a task by threads.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### **SEGMENTATION**

• An important aspect of memory management that became unavoidable with paging is the separation of the user's view of memory from the actual physical memory. As we have already seen, the user's view of memory is not the same as the actual physical memory. The user's view is mapped onto physical memory. This mapping allows differentiation between logical memory and physical memory.

### **Basic Methods**

• It is a memory-management scheme that supports this user view of memory. A logical address space is a collection of segments. Each segment has a name and a length. The addresses specify both the segment name and the offset within the segment. The user therefore specifies each address by two quantities: a segment name and an offset. (Contrast this scheme with the paging scheme, in which the user specifies only a single address, which is partitioned by the hardware into a page number and an offset, all invisible to the programmer.) For simplicity of implementation, segments are numbered and are referred to by a segn"lent number, rather than by a segment name. Thus, a logical address consists of a two tuple:

<segment-number, offset>.

- Normally, the user program is compiled, and the compiler automatically constructs segments reflecting the input program. A C compiler might create segarate segments for the following:
  - 1. The code
  - 2. Global variables
  - 3. The heap, from which memory is allocated
  - 4. The stacks used by each thread
  - 5. The standard C library
- Libraries that are linked in during compile time might be assigned separate segments. The loader would take all these segments and assign them segment numbers.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### <u>Hardware</u>

• Although the user can now refer to objects in the program by a two-dimensional address, the actual physical memory is still, of course, a one-dimensional sequence of bytes. Thus, we must define an implementation to map two dimensional user-defined addresses into one-dimensional physical addresses. This mapping is affected by each entry in the segment table has a segment base and a segment limit. The segment base contains the start physical address where the segment resides in memory, and the segment limit specifies the length of the segment. The use of a segment table is illustrated in Figure

• A logical address consists of two parts: a segment number, s, and an offset into that segment, d. the segment number is used as an index to the segment table. The offset d of the logical address must be between 0 and the segment limit. If it is not, we trap to the operating system (logical addressing attempt beyond end of segment). When an offset is legal, it is added to the segment base to produce the address in physical memory of the desired byte. The segment table is thus essentially an array of base-limit register pairs. As an example, consider the situation shown in Figure

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

We have five segments numbered from 0 through 4. The segments are stored in physical memory as shown. The segment table has a separate entry for each segment, giving the beginning address of the segment in physical memory (or base) and the length of that segment (or limit). For example, segment 2 is 400 bytes long and begins at location 4300. Thus, a reference to byte 53 of segment 2 is mapped onto location 4300 +53= 4353. A reference to segment 3, byte 852, is mapped to 3200 (the base of segment 3) + 852 = 4052. A reference to byte 1222 of segment 0 would result in a trap to the operating system, as this segment is only 1000 bytes long.

#### Segmentation and Paging

• A user program can be subdivided using segmentation, in which the program and its associated data are divided into a number of **segments.** It is not required that all segments of all programs be of the same length, although there is a maximum segment length. As with paging, a logical address using segmentation consists of two parts, in this case a

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

segment number and an offset. Because of the use of unequal-size segments, segmentation is similar to dynamic partitioning.

- In the absence of an overlay scheme or the use of virtual memory, it would be required that all of a program's segments be loaded into memory for execution. The difference, compared to dynamic partitioning, is that with segmentation a program may occupy more than one partition, and these partitions need not be contiguous. Segmentation eliminates internal fragmentation but, like dynamic partitioning, it suffers from external fragmentation.
- However, because a process is broken up into a number of smaller pieces, the external fragmentation should be less. Whereas paging is invisible to the programmer, segmentation is usually visible and is provided as a convenience for organizing programs and data. STypically, the programmer or compiler will assign programs and data to different segments. For purposes of modular programming, the program or data may be further broken down into multiple segments.
- The principal inconvenience of this service is that the programmer must be aware of the maximum segment size limitation. Another consequence of unequal-size segments is that there is no simple relationship between logical addresses and physical addresses.
- Each segment table entry would have to give the starting address in main memory of the corresponding segment. The entry should also provide the length of the segment, to assure that invalid addresses are not used. When a process enters the Running state, the address of its segment table is loaded into a special register used by the memory management hardware. Consider an address of n\_m bits, where the leftmost n bits are the segment number and the rightmost m bits are the offset. In our example (Figure C), n\_4 and m\_12. Thus the maximum segment size is 2 12 \_ 4096.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

The following steps are needed for address translation:

• Extract the segment number as the leftmost n bits of the logical address.

• Use the segment number as an index into the process segment table to find the starting physical address of the segment.

• Compare the offset, expressed in the rightmost m bits, to the length of the segment.

If the offset is greater than or equal to the length, the address is invalid. The desired physical address is the sum of the starting physical address of the segment plus the offset.

To summarize, with simple segmentation, a process is divided into a number of segments that need not be of equal size. When a process is brought in, all of its segments are loaded into available regions of memory, and a segment table is set up.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

## VIRTUAL MEMORY

### Virtual Memory and its Organization

- Virtual memory is a technique that allows the execution of processes which are not completely available in memory. The main visible advantage of this scheme is that programs can be larger than physical memory. Virtual memory is the separation of user logical memory from physical memory. This separation allows an extremely large virtual memory to be provided for programmers when only a smaller physical memory is available. Following are the situations, when entire program is not required to be loaded fully in main memory.
- User written error handling routines are used only when an error occured in the data or computation.
- Certain options and features of a program may be used rarely.
- Many tables are assigned a fixed amount of address space even though only a small amount of the table is actually used.
- The ability to execute a program that is only partially in memory would counter many benefits.
- Less number of I/O would be needed to load or swap each user program into memory.
- A program would no longer be constrained by the amount of physical memory that is available.
- Each user program could take less physical memory, more programs could be run the same time, with a corresponding increase in CPU utilization and throughput.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• Virtual memory is commonly implemented by demand paging. It can also be implemented in a segmentation system. Demand segmentation can also be used to provide virtual memory.

### **Demand Paging**

- A demand paging system is quite similar to a paging system with swapping. When we want to execute a process, we swap it into memory. Rather than swapping the entire process into memory, however, we use a lazy swapper called pager.
- When a process is to be swapped in, the pager, guesses which pages will be used before the process is swapped out again. Instead of swapping in a whole process, the pager brings only those necessary pages into memory. Thus, it avoids reading into memory pages that will not be used in anyway, decreasing the swap time and the amount of physical memory needed.
- Hardware support is required to distinguish between those pages that are in memory and those pages that are on the disk using the valid-invalid bit scheme, where valid and invalid pages can be checked by checking the bit. Marking a page will have no effect if the process never attempts to access the page. While the process executes and accesses pages that are memory resident, execution proceeds normally.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• Access to a page marked invalid causes a page-fault trap. This trap is the result of the operating system's failure to bring the desired page into memory. But page fault can be handled as following

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

Step	Description
Step 1	Check an internal table for this process, to determine whether the reference was a valid or it was an invalid memory access.
Step 2	If the reference was invalid, terminate the process. If it was valid, but page have not yet brought in, page in the latter.
Step 3	Find a free frame.
Step 4	Schedule a disk operation to read the desired page into the newly allocated frame.
Step 5	When the disk read is complete, modify the internal table kept with the process and the page table to indicate that the page is now in memory.
Step 6	Restart the instruction that was interrupted by the illegal address trap. The process can now access the page as though it had always been in memory. Therefore, the operating system reads the desired page into memory and restarts the process as though the page had always been in memory.

### > Advantages

Following are the advantages of Demand Paging

- Large virtual memory.
- More efficient use of memory.
- Unconstrained multiprogramming. There is no limit on degree of multiprogramming.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### > Disadvantages

Following are the disadvantages of Demand Paging

- Number of tables and amount of processor overhead for handling page interrupts are greater than in the case of the simple paged management techniques.
- Due to the lack of an explicit constraint on a job address space size.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

## POSSIBLE QUESTIONS UNIT – III PART – A (20 MARKS) (Q.NO 1 TO 20 Online Examinations)

## PART – B (2 MARKS)

- 1. What do you mean by granting right?
- 2. What is user management commands?
- 3. What is File Quota?
- 4. Define File Layout.
- 5. What do you mean by managing disk quotas?
- 6. Define symbolic link.

### PART – C (6 MARKS)

- 1. Explain the types of users.
- 2. Explain the user management commands.
- 3. Explain the file quota and various file systems available.
- 4. Discuss the file system management and layout.
- 5. Explain the file permissions.
- 6. Discuss the login process.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

# <u>UNIT – III</u> SYLLABUS

**User Management and the File System** Types of Users, Creating users, Granting rights User management commands, File quota and various file systems available, File System Management and Layout, File permissions, Login process, Managing Disk Quotas, Links (hard links, symbolic links)

- The operating system, executing in kernel mode, is given unrestricted access to both operating-system memory and users' memory. This provision allows the operating system to load users' programs into users' memory, to dump out those programs in case of errors, to access and modify parameters of system calls, to perform I/O to and from user memory, and to provide many other services.
- Consider, for example, that an operating system for a multiprocessing system must execute context switches, storing the state of one process from the registers into main memory before loading the next process's context from main memory into the registers. This scheme allows the operating system to change the value of the registers but prevents user programs from changing the registers' contents.

### Address Binding

- Memory management is the functionality of an operating system which handles or manages primary memory. Memory management keeps track of each and every memory location either it is allocated to some process or it is free. It checks how much memory is to be allocated to processes. It decides which process will get memory at what time. It tracks whenever some memory gets freed or unallocated and correspondingly it updates the status.
- Memory management provides protection by using two registers, a base register and a limit register. The base register holds the smallest legal physical memory address and the limit register specifies the size of the range. For example, if the base register holds 300000 and the limit register is 1209000, then the program can legally access all addresses from 300000 through 411999.

Instructions and data to memory addresses can be done in following ways

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- Compile time -- When it is known at compile time where the process will reside, compile time binding is used to generate the absolute code.
- Load time -- When it is not known at compile time where the process will reside in memory, then the compiler generates re-locatable code.
- Execution time -- If the process can be moved during its execution from one memory segment to another, then binding must be delayed to be done at run time

### **Dynamic Loading**

- In dynamic loading, a routine of a program is not loaded until it is called by the program. All routines are kept on disk in a re-locatable load format. The main program is loaded into memory and is executed. Other routines methods or modules are loaded on request. Dynamic loading makes better memory space utilization and unused routines are never loaded.
- The advantage of dynamic loading is that a routine is loaded only when it is needed. This method is particularly useful when large amounts of code are needed to handle infrequently occurring cases, such as error routines. In this case, although the total program size may be large, the portion that is used (and hence loaded) may be much smaller.
- Dynamic loading does not require special support from the operating system. It is the
  responsibility of the users to design their programs to take advantage of such a method.
  Operating systems may help the programmer, however, by providing library routines to
  implement dynamic loading.

#### **Dynamic Linking**

• Linking is the process of collecting and combining various modules of code and data into a executable file that can be loaded into memory and executed. Operating system can link system level libraries to a program. When it combines the libraries at load time, the linking is called static linking and when this linking is done at the time of execution, it is called as dynamic linking.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- In static linking, libraries linked at compile time, so program code size becomes bigger whereas in dynamic linking libraries linked at execution time so program code size remains smaller.
- Unlike dynamic loading, dynamic linking and shared libraries generally require help from the operating system. If the processes in memory are protected from one another, then the operating system is the only entity that can check to see whether the needed routine is in another process's memory space or that can allow multiple processes to access the same memory addresses.

#### PHYSICAL AND VIRTUAL ADDRESS SPACE

#### Logical (Virtual) versus Physical Address Space

An address generated by the CPU is a logical address whereas address actually available on memory unit is a physical address. Logical address is also known a Virtual address. Virtual and physical addresses are the same in compile-time and load-time address-binding schemes. Virtual and physical addresses differ in execution-time address-binding scheme.

The set of all logical addresses generated by a program is referred to as a logical address space. The set of all physical addresses corresponding to these logical addresses is referred to as a physical address space.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

The run-time mapping from virtual to physical address is done by the memory management unit (MMU) which is a hardware device.

MMU uses following mechanism to convert virtual address to physical address.

- The value in the base register is added to every address generated by a user process which is treated as offset at the time it is sent to memory. For example, if the base register value is 10000, then an attempt by the user to use address location 100 will be dynamically reallocated to location 10100.
- The user program deals with virtual addresses; it never sees the real physical addresses.

### **MEMORY ALLOCATION STRATEGIES**

### **Contiguous Memory Allocation**

- The main memory must accommodate both the operating system and the various user processes. We therefore need to allocate main memory in the most efficient way possible. The memory is usually divided into two partitions: one for the resident operating system and one for the user processes.
- We can place the operating system in either low memory or high memory. The major factor affecting this decision is the location of the interrupt vector. Since the interrupt vector is often in low memory, programmers usually place the operating system in low memory as well.
- We usually want several user processes to reside in memory at the same time. We therefore need to consider how to allocate available memory to the processes that are in the input queue waiting to be brought into memory. In contiguous memory allocation, each process is contained in a single section of memory that is contiguous to the section containing the next process.

### **Memory Protection**

• Before discussing memory allocation further, we must discuss the issue of memory protection. If we have a system with a relocation register, together with a limit, we accomplish our goal. The relocation register contains the value of the smallest physical

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

address; the limit register contains the range of logical addresses (for example, relocation = 100040 and limit = 74600).

• Each logical address must fall within the range specified by the limit register. The MMU maps the logical address dynamically by adding the value in the relocation register. This mapped address is sent to memory. When the CPU scheduler selects a process for execution, the dispatcher loads the relocation and limit registers with the correct values as part of the context switch. Because every address generated by a CPU is checked against these registers, we can protect both the operating system and the other users' programs and data from being modified by this running process.

### **Memory Allocation**

- One of the simplest methods for allocating memory is to divide memory into several fixedsized **partitions**. Each partition may contain exactly one process. Thus, the degree of multiprogramming is bound by the number of partitions. In this multiple **partition method**, when a partition is free, a process is selected from the input queue and is loaded into the free partition.
- When the process terminates, the partition becomes available for another process. This
  method was originally used by the IBM OS/360 operating system (called MFT) but is no
  longer in use. The method described next is a generalization of the fixed-partition scheme
  (called MVT); it is used primarily in batch environments. Many of the ideas presented here
  are also applicable to a time-sharing environment in which pure segmentation is used for
  memory management.
- In the variable-partition scheme, the operating system keeps a table indicating which parts of memory are available and which are occupied. Initially, all memory is available for user processes and is considered one large block of available memory, a hole. Eventually, as you will see, memory contains a set of holes of various sizes.
- As processes enter the system, they are put into an input queue. The operating system takes into account the memory requirements of each process and the amount of available memory space in determining which processes are allocated memory.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- When a process is allocated space, it is loaded into memory, and it can then compete for CPU time. When a process terminates, it releases its memory, which the operating system may then fill with another process from the input queue.
- In general, the memory blocks available comprise a set of holes of various sizes scattered throughout memory. When a process arrives and needs memory, the system searches the set for a hole that is large enough for this process. If the hole is too large, it is split into two parts. One part is allocated to the arriving process; the other is returned to the set of holes. When a process terminates, it releases its block of memory, which is then placed back in the set of holes.
- If the new hole is adjacent to other holes, these adjacent holes are merged to form one larger hole. At this point, the system may need to check whether there are processes waiting for memory and whether this newly freed and recombined memory could satisfy the demands of any of these waiting processes. This procedure is a particular instance of the general dynamic storage allocation problem, which concerns how to satisfy a request of size n from a list of free holes. There are many solutions to this problem. The first-fit, best-fit, and worst-fit strategies are the ones most commonly used to select a free hole from the set of available holes.

• First fit. Allocate the first hole that is big enough. Searching can start either at the beginning of the set of holes or at the location where the previous first-fit search ended. We can stop searching as soon as we find a free hole that is large enough.

• **Best fit.** Allocate the smallest hole that is big enough. We must search the entire list, unless the list is ordered by size. This strategy produces the smallest leftover hole.

• Worst fit. Allocate the largest hole. Again, we must search the entire list, unless it is sorted by size. This strategy produces the largest leftover hole, which may be more useful than the smaller leftover hole from a best-fit approach.

#### **Fragmentation**

• Both the first-fit and best-fit strategies for memory allocation suffer from **external fragmentation.** As processes are loaded and removed from memory, the free memory space is broken into little pieces. External fragmentation exists when there is enough total memory

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

space to satisfy a request but the available spaces are not contiguous: storage is fragmented into a large number of small holes. This fragmentation problem can be severe. In the worst case, we could have a block of free (or wasted) memory between every two processes. If all these small pieces of memory were in one big free block instead, we might be able to run several more processes.

- Whether we are using the first-fit or best-fit strategy can affect the amount of fragmentation. (First fit is better for some systems, whereas best fit is better for others.) Another factor is which end of a free block is allocated. (Which is the leftover piece—the one on the top or the one on the bottom?) Memory fragmentation can be internal as well as external. Consider a multiple-partition allocation scheme with a hole of 18,464 bytes. Suppose that the next process requests 18,462 bytes. If we allocate exactly the requested block, we are left with a hole of 2 bytes. The overhead to keep track of this hole will be substantially larger than the hole itself.
- The general approach to avoiding this problem is to break the physical memory into fixedsized blocks and allocate memory in units based on block size. With this approach, the memory allocated to a process may be slightly larger than the requested memory. The difference between these two numbers is **internal fragmentation**—unused memory that is internal to a partition.
- One solution to the problem of external fragmentation is compaction. The goal is to shuffle the memory contents so as to place all free memory together in one large block. Compaction is not always possible, however. If relocation is static and is done at assembly or load time, compaction cannot be done. It is possible only if relocation is dynamic and is done at execution time. Another possible solution to the external-fragmentation problem is to permit the logical address space of the processes to be noncontiguous, thus allowing a process to be allocated physical memory wherever such memory is available. Two complementary techniques achieve this solution: segmentation and paging

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

## **PAGING**

- It is a memory-management scheme that permits the physical address space a process to be noncontiguous. Paging avoids external fragmentation and the need for compaction. It also solves the considerable problem of fitting memory chunks of varying sizes onto the backing store; most memory management schemes used before the introduction of paging suffered from this problem. The problem arises because, when some code fragments or data residing in main memory need to be swapped out, space must be framed on the backing store.
- The backing store has the same fragmentation problems discussed in connection with main memory, but access is much slower, so compaction is impossible. Because of its advantages over earlier methods, paging in its various forms is used in most operating systems.

Traditionally, support for paging has been handled by hardware. However, recent designs have implemented paging by closely integrating the hardware and operating system, especially on 64-bit microprocessors.

### **Basic Method**

- The basic method for implementing paging involves breaking physical memory into fixedsized blocks called frames and breaking logical memory into blocks of the same size called pages.
- When a process is to be executed, its pages are loaded into any available memory frames from their source (a file system or the backing store). The backing store is divided into fixed-sized blocks that are of the san1.e size as the memory frames. The hardware support for paging is illustrated in the following figure

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• Every address generated the CPU is divided into two parts: a {p) and a . The page number is used as an index into a page table contains the base address of each page in physical memory. This base address is combined with the page offset to define the physical memory address that is sent to the memory unit. The paging model of memory is shown in the following diagram

• The page size (like the frame size) is defined by the hardware. The size of a page is typically a power of 2, varying between 512 bytes and 16 MB per page, depending on the computer architecture. The selection of a power of 2 as a page size makes the translation of a logical address into a page number and page offset particularly easy.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

page number	page offset
р	d
m-n	п

• If the size of the logical address space is 2m, and a page size is 271 addressing units (bytes or wordst then the high-order m- n bits of a logical address designate the page number, and the n low-order bits designate the page offset. Thus, the logical address is as follows: where p is an index into the page table and d is the displacement within the page. As a concrete (although minuscule) example, consider the memory in the following diagram

- Here, in the logical address, n= 2 and m = 4. Using a page size of 4 bytes and a physical memory of 32 bytes (8 pages), we show how the user's view of memory can be mapped into physical memory. Logical address 0 is page 0, offset 0. Indexing into the page table, we find that page 0 is in frame 5. Thus, logical address 0 maps to physical address 20 [= (5 x 4) + 0]. Logical address 3 (page 0, offset 3) maps to physical address 23 [ = (5 x 4) + 3].
- Logical address 4 is page 1, offset 0; according to the page table, page 1 is mapped to frame
   6. Thus, logical address 4 maps to physical address 24 [ = ( 6 x 4) + O]. Logical address 13 maps to physical address 9. You may have noticed that paging itself is a form of dynamic relocation. Every logical address is bound by the paging hardware to some physical address.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

Using paging is similar to using a table of base (or relocation) registers, one for each frame of memory. When we use a paging scheme, we have no external fragmentation: any free frame can be allocated to a process that needs it. However, we may have some internal fragmentation. Notice that frames are allocated as units.

- If the memory requirements of a process do not happen to coincide with page boundaries, the last frame allocated may not be completely full. For example, if page size is 2,048 bytes, a process of 72,766 bytes will need 35 pages plus 1,086 bytes. It will be allocated 36 frames, resulting in internal fragmentation of 2,048 1,086 = 962 bytes. In the worst case, a process would need 11 pages plus 1 byte. It would be allocated 11 + 1 frames, resulting in internal fragmentation of almost an entire frame. If process size is independent of page size, we expect internal fragmentation to average one-half page per process. This consideration suggests that small page sizes are desirable. Generally, page sizes have grown over time as processes, data sets, and main memory have become larger.
- Today, pages typically are between 4 KB and 8 KB in size and some systems support even larger page sizes. Some CPUs and kernels even support multiple page sizes. For instance, Solaris uses page sizes of 8 KB and 4 MB, depending on the data stored by the pages. Researchers are now developing support for variable on-the-fly page size. Usually, each page-table entry is 4 bytes long, but that size can vary as well. A 32-bit entry can point to one of 232 physical page frames. If frame size is 4 KB, then a system with 4-byte entries can address 244 bytes (or 16 TB) of physical memory. When a process arrives in the system to be executed, its size, expressed in pages, is examined. Each page of the process needs one frame. Thus, if the process requires 11 pages, at least 11 frames must be available in memory.
- If n frames are available, they are allocated to this arriving process. The first page of the process is loaded into one of the allocated frames, and the frame number is put in the page table for this process. The next page is loaded into another frame, its frame number is put into the page table, and so on. An important aspect of paging is the clear separation between the user's view of memory and the actual physical memory. The user program views

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

memory as one single space, containing only this one program. In fact, the user program is scattered throughout physical memory, which also holds other programs.

- The difference between the user's view of memory and the actual physical memory is reconciled by the address-translation hardware. The logical addresses are translated into physical addresses. This mapping is hidden from the user and is controlled by the operating system. Notice that the user process by definition is unable to access memory it does not own.
- It has no way of addressing memory outside of its page table, and the table includes only those pages that the process owns. Since the operating system is managing physical memory, it must be aware of the allocation details of physical memory-which frames are allocated, which frames are available, how many total frames there are, and so on. This information is generally kept in a data structure called a frame the frame-table has one entry for each physical page frame, indicating whether the latter is free or allocated and, if it is allocated, to which page of which process or processes.
- In addition, the operating system must be aware that user processes operate in user space, and all logical addresses must be mapped to produce physical addresses. If a user makes a system call (to do I/0, for example) and provides an address as a parameter (a buffe1~ for instance), that address must be mapped to produce the correct physical address.
- The operating system maintains a copy of the page table for each process, just as it maintains a copy of the instruction counter and register contents. This copy is used to translate logical addresses to physical addresses whenever the operating system must map a logical address to a physical address manually. It is also used by the CPU dispatcher to define the hardware page table when a process is to be allocated the CPU. Paging therefore increases the context-switch time.

#### **STRUCTURE OF PAGE TABLE**

In this section, we explore some of the most common techniques for structuring the page table, including hierarchical paging, hashed page tables, and inverted page tables.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### **Hierarchical Paging**

• Most modern computer systems support a large logical address space (232 to 264). In such an environment, the page table itself becomes excessively large. For example, consider a system with a 32-bit logical address space. If the page size in such a system is 4 KB (212), then a page table may consist of up to 1 million entries (232/212). Assuming that each entry consists of 4 bytes, each process may need up to 4 MB of physical address space for the page table alone. Clearly, we would not want to allocate the page table contiguously in main memory. One simple solution to this problem is to divide the page table into smaller pieces.

• We can accomplish this division in several ways. One way is to use a two-level paging algorithm, in which the page table itself is also paged. For example, consider again the system with a 32-bit logical address space and a page size of 4 KB. A logical address is divided into a page number

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

consisting of 20 bits and a page offset consisting of 12 bits. Because we page the page table, the page number is further divided into a 10-bit page number and a 10-bit page offset. Thus, a logical address is as follows:

Where p1 is an index into the outer page table and p2 is the displacement within the page of the inner page table. The address-translation method for this architecture is shown in Figure. Because address translation works from the outer page table inward, this scheme is also known as a forward-mapped page table.

### Hashed Page Tables

- A common approach for handling address spaces larger than 32 bits is to use a hashed page table, with the hash value being the virtual page number. Each entry in the hash table contains a linked list of elements that hash to the same location (to handle collisions). Each element consists of three fields: (1) the virtual page number, (2) the value of the mapped page frame, and (3) a pointer to the next element in the linked list. The algorithm works as follows:
- The virtual page number in the virtual address is hashed into the hash table. The virtual page number is compared with field 1 in the first element in the linked list. If there is a match, the corresponding page frame (field 2) is used to form the desired physical address. If there is no match, subsequent entries in the linked list are searched for a matching virtual page number.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

#### **Inverted Page Tables**

- Usually, each process has an associated page table. The page table has one entry for each page that the process is using (or one slot for each virtual address, regardless of the latter's validity). This table representation is a natural one, since processes reference pages through the pages' virtual addresses.
- The operating system must then translate this reference into a physical memory address. Since the table is sorted by virtual address, the operating system is able to calculate where in the table the associated physical address entry is located and to use that value directly. One of the drawbacks of this method is that each page table may consist of millions of entries. These tables may consume large amounts of physical memory just to keep track of how other physical memory is being used.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• To solve this problem, we can use an inverted page table. An inverted page table has one entry for each real page (or frame) of memory. Each entry consists of the virtual address of the page stored in that real memory location, with information about the process that owns the page. Thus, only one page table is in the system, and it has only one entry for each page of physical memory.

#### **Shared Pages**

• An advantage of paging is the possibility of sharing common code. This consideration is particularly important in a time-sharing environment. Consider a system that supports 40 users, each of whom executes a text editor. If the text editor consists of 150 KB of code and 50 KB of data space, we need 8,000 KB to support the 40 users. If the code is reentrant code (or pure code), it can be shared, as shown in Figure. Here, we see three processes sharing a three-page editor—each page 50 KB in size (the large page size is used to simplify the figure). Each process has its own data page. Reentrant code is non-self-modifying code: it never changes during execution. Thus, two or more processes can execute the same code at the same time.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- Each process has its own copy of registers and data storage to hold the data for the process's execution. The data for two different processes will, of course, be different. Only one copy of the editor need be kept in physical memory. Each user's page table maps onto the same physical copy of the editor, but data pages are mapped onto different frames. Thus, to support 40 users, we need only one copy of the editor (150 KB), plus 40 copies of the 50 KB of data space per user. The total space required is now 2,150 KB instead of 8,000 KB—a significant savings. Other heavily used programs can also be shared—compilers, window systems, run-time libraries, database systems, and so on. To be sharable, the code must be reentrant. The read-only nature of shared code should not be left to the correctness of the code; the operating system should enforce this property.
- The sharing of memory among processes on a system is similar to the sharing of the address space of a task by threads.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### **SEGMENTATION**

• An important aspect of memory management that became unavoidable with paging is the separation of the user's view of memory from the actual physical memory. As we have already seen, the user's view of memory is not the same as the actual physical memory. The user's view is mapped onto physical memory. This mapping allows differentiation between logical memory and physical memory.

### **Basic Methods**

• It is a memory-management scheme that supports this user view of memory. A logical address space is a collection of segments. Each segment has a name and a length. The addresses specify both the segment name and the offset within the segment. The user therefore specifies each address by two quantities: a segment name and an offset. (Contrast this scheme with the paging scheme, in which the user specifies only a single address, which is partitioned by the hardware into a page number and an offset, all invisible to the programmer.) For simplicity of implementation, segments are numbered and are referred to by a segn"lent number, rather than by a segment name. Thus, a logical address consists of a two tuple:

<segment-number, offset>.

- Normally, the user program is compiled, and the compiler automatically constructs segments reflecting the input program. A C compiler might create segarate segments for the following:
  - 1. The code
  - 2. Global variables
  - 3. The heap, from which memory is allocated
  - 4. The stacks used by each thread
  - 5. The standard C library
- Libraries that are linked in during compile time might be assigned separate segments. The loader would take all these segments and assign them segment numbers.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### <u>Hardware</u>

• Although the user can now refer to objects in the program by a two-dimensional address, the actual physical memory is still, of course, a one-dimensional sequence of bytes. Thus, we must define an implementation to map two dimensional user-defined addresses into one-dimensional physical addresses. This mapping is affected by each entry in the segment table has a segment base and a segment limit. The segment base contains the start physical address where the segment resides in memory, and the segment limit specifies the length of the segment. The use of a segment table is illustrated in Figure

• A logical address consists of two parts: a segment number, s, and an offset into that segment, d. the segment number is used as an index to the segment table. The offset d of the logical address must be between 0 and the segment limit. If it is not, we trap to the operating system (logical addressing attempt beyond end of segment). When an offset is legal, it is added to the segment base to produce the address in physical memory of the desired byte. The segment table is thus essentially an array of base-limit register pairs. As an example, consider the situation shown in Figure

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

We have five segments numbered from 0 through 4. The segments are stored in physical memory as shown. The segment table has a separate entry for each segment, giving the beginning address of the segment in physical memory (or base) and the length of that segment (or limit). For example, segment 2 is 400 bytes long and begins at location 4300. Thus, a reference to byte 53 of segment 2 is mapped onto location 4300 +53= 4353. A reference to segment 3, byte 852, is mapped to 3200 (the base of segment 3) + 852 = 4052. A reference to byte 1222 of segment 0 would result in a trap to the operating system, as this segment is only 1000 bytes long.

#### Segmentation and Paging

• A user program can be subdivided using segmentation, in which the program and its associated data are divided into a number of **segments.** It is not required that all segments of all programs be of the same length, although there is a maximum segment length. As with paging, a logical address using segmentation consists of two parts, in this case a

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

segment number and an offset. Because of the use of unequal-size segments, segmentation is similar to dynamic partitioning.

- In the absence of an overlay scheme or the use of virtual memory, it would be required that all of a program's segments be loaded into memory for execution. The difference, compared to dynamic partitioning, is that with segmentation a program may occupy more than one partition, and these partitions need not be contiguous. Segmentation eliminates internal fragmentation but, like dynamic partitioning, it suffers from external fragmentation.
- However, because a process is broken up into a number of smaller pieces, the external fragmentation should be less. Whereas paging is invisible to the programmer, segmentation is usually visible and is provided as a convenience for organizing programs and data. STypically, the programmer or compiler will assign programs and data to different segments. For purposes of modular programming, the program or data may be further broken down into multiple segments.
- The principal inconvenience of this service is that the programmer must be aware of the maximum segment size limitation. Another consequence of unequal-size segments is that there is no simple relationship between logical addresses and physical addresses.
- Each segment table entry would have to give the starting address in main memory of the corresponding segment. The entry should also provide the length of the segment, to assure that invalid addresses are not used. When a process enters the Running state, the address of its segment table is loaded into a special register used by the memory management hardware. Consider an address of n\_m bits, where the leftmost n bits are the segment number and the rightmost m bits are the offset. In our example (Figure C), n\_4 and m\_12. Thus the maximum segment size is 2 12 \_ 4096.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

The following steps are needed for address translation:

• Extract the segment number as the leftmost n bits of the logical address.

• Use the segment number as an index into the process segment table to find the starting physical address of the segment.

• Compare the offset, expressed in the rightmost m bits, to the length of the segment.

If the offset is greater than or equal to the length, the address is invalid. The desired physical address is the sum of the starting physical address of the segment plus the offset.

To summarize, with simple segmentation, a process is divided into a number of segments that need not be of equal size. When a process is brought in, all of its segments are loaded into available regions of memory, and a segment table is set up.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### VIRTUAL MEMORY

### Virtual Memory and its Organization

- Virtual memory is a technique that allows the execution of processes which are not completely available in memory. The main visible advantage of this scheme is that programs can be larger than physical memory. Virtual memory is the separation of user logical memory from physical memory. This separation allows an extremely large virtual memory to be provided for programmers when only a smaller physical memory is available. Following are the situations, when entire program is not required to be loaded fully in main memory.
- User written error handling routines are used only when an error occured in the data or computation.
- Certain options and features of a program may be used rarely.
- Many tables are assigned a fixed amount of address space even though only a small amount of the table is actually used.
- The ability to execute a program that is only partially in memory would counter many benefits.
- Less number of I/O would be needed to load or swap each user program into memory.
- A program would no longer be constrained by the amount of physical memory that is available.
- Each user program could take less physical memory, more programs could be run the same time, with a corresponding increase in CPU utilization and throughput.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• Virtual memory is commonly implemented by demand paging. It can also be implemented in a segmentation system. Demand segmentation can also be used to provide virtual memory.

### **Demand Paging**

- A demand paging system is quite similar to a paging system with swapping. When we want to execute a process, we swap it into memory. Rather than swapping the entire process into memory, however, we use a lazy swapper called pager.
- When a process is to be swapped in, the pager, guesses which pages will be used before the process is swapped out again. Instead of swapping in a whole process, the pager brings only those necessary pages into memory. Thus, it avoids reading into memory pages that will not be used in anyway, decreasing the swap time and the amount of physical memory needed.
- Hardware support is required to distinguish between those pages that are in memory and those pages that are on the disk using the valid-invalid bit scheme, where valid and invalid pages can be checked by checking the bit. Marking a page will have no effect if the process never attempts to access the page. While the process executes and accesses pages that are memory resident, execution proceeds normally.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• Access to a page marked invalid causes a page-fault trap. This trap is the result of the operating system's failure to bring the desired page into memory. But page fault can be handled as following

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

Step	Description
Step 1	Check an internal table for this process, to determine whether the reference was a valid or it was an invalid memory access.
Step 2	If the reference was invalid, terminate the process. If it was valid, but page have not yet brought in, page in the latter.
Step 3	Find a free frame.
Step 4	Schedule a disk operation to read the desired page into the newly allocated frame.
Step 5	When the disk read is complete, modify the internal table kept with the process and the page table to indicate that the page is now in memory.
Step 6	Restart the instruction that was interrupted by the illegal address trap. The process can now access the page as though it had always been in memory. Therefore, the operating system reads the desired page into memory and restarts the process as though the page had always been in memory.

### > Advantages

Following are the advantages of Demand Paging

- Large virtual memory.
- More efficient use of memory.
- Unconstrained multiprogramming. There is no limit on degree of multiprogramming.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### > Disadvantages

Following are the disadvantages of Demand Paging

- Number of tables and amount of processor overhead for handling page interrupts are greater than in the case of the simple paged management techniques.
- Due to the lack of an explicit constraint on a job address space size.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- 3. What is File Quota?
- 4. Define File Layout.
- 5. What do you mean by managing disk quotas?
- 6. Define symbolic link.

### PART – C (6 MARKS)

- 1. Explain the types of users.
- 2. Explain the user management commands.
- 3. Explain the file quota and various file systems available.
- 4. Discuss the file system management and layout.
- 5. Explain the file permissions.
- 6. Discuss the login process.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

# <u>UNIT – III</u> SYLLABUS

**User Management and the File System** Types of Users, Creating users, Granting rights User management commands, File quota and various file systems available, File System Management and Layout, File permissions, Login process, Managing Disk Quotas, Links (hard links, symbolic links)

- The operating system, executing in kernel mode, is given unrestricted access to both operating-system memory and users' memory. This provision allows the operating system to load users' programs into users' memory, to dump out those programs in case of errors, to access and modify parameters of system calls, to perform I/O to and from user memory, and to provide many other services.
- Consider, for example, that an operating system for a multiprocessing system must execute context switches, storing the state of one process from the registers into main memory before loading the next process's context from main memory into the registers. This scheme allows the operating system to change the value of the registers but prevents user programs from changing the registers' contents.

### Address Binding

- Memory management is the functionality of an operating system which handles or manages primary memory. Memory management keeps track of each and every memory location either it is allocated to some process or it is free. It checks how much memory is to be allocated to processes. It decides which process will get memory at what time. It tracks whenever some memory gets freed or unallocated and correspondingly it updates the status.
- Memory management provides protection by using two registers, a base register and a limit register. The base register holds the smallest legal physical memory address and the limit register specifies the size of the range. For example, if the base register holds 300000 and the limit register is 1209000, then the program can legally access all addresses from 300000 through 411999.

Instructions and data to memory addresses can be done in following ways

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- Compile time -- When it is known at compile time where the process will reside, compile time binding is used to generate the absolute code.
- Load time -- When it is not known at compile time where the process will reside in memory, then the compiler generates re-locatable code.
- Execution time -- If the process can be moved during its execution from one memory segment to another, then binding must be delayed to be done at run time

### **Dynamic Loading**

- In dynamic loading, a routine of a program is not loaded until it is called by the program. All routines are kept on disk in a re-locatable load format. The main program is loaded into memory and is executed. Other routines methods or modules are loaded on request. Dynamic loading makes better memory space utilization and unused routines are never loaded.
- The advantage of dynamic loading is that a routine is loaded only when it is needed. This method is particularly useful when large amounts of code are needed to handle infrequently occurring cases, such as error routines. In this case, although the total program size may be large, the portion that is used (and hence loaded) may be much smaller.
- Dynamic loading does not require special support from the operating system. It is the
  responsibility of the users to design their programs to take advantage of such a method.
  Operating systems may help the programmer, however, by providing library routines to
  implement dynamic loading.

#### **Dynamic Linking**

• Linking is the process of collecting and combining various modules of code and data into a executable file that can be loaded into memory and executed. Operating system can link system level libraries to a program. When it combines the libraries at load time, the linking is called static linking and when this linking is done at the time of execution, it is called as dynamic linking.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- In static linking, libraries linked at compile time, so program code size becomes bigger whereas in dynamic linking libraries linked at execution time so program code size remains smaller.
- Unlike dynamic loading, dynamic linking and shared libraries generally require help from the operating system. If the processes in memory are protected from one another, then the operating system is the only entity that can check to see whether the needed routine is in another process's memory space or that can allow multiple processes to access the same memory addresses.

#### PHYSICAL AND VIRTUAL ADDRESS SPACE

#### Logical (Virtual) versus Physical Address Space

An address generated by the CPU is a logical address whereas address actually available on memory unit is a physical address. Logical address is also known a Virtual address. Virtual and physical addresses are the same in compile-time and load-time address-binding schemes. Virtual and physical addresses differ in execution-time address-binding scheme.

The set of all logical addresses generated by a program is referred to as a logical address space. The set of all physical addresses corresponding to these logical addresses is referred to as a physical address space.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

The run-time mapping from virtual to physical address is done by the memory management unit (MMU) which is a hardware device.

MMU uses following mechanism to convert virtual address to physical address.

- The value in the base register is added to every address generated by a user process which is treated as offset at the time it is sent to memory. For example, if the base register value is 10000, then an attempt by the user to use address location 100 will be dynamically reallocated to location 10100.
- The user program deals with virtual addresses; it never sees the real physical addresses.

### **MEMORY ALLOCATION STRATEGIES**

### **Contiguous Memory Allocation**

- The main memory must accommodate both the operating system and the various user processes. We therefore need to allocate main memory in the most efficient way possible. The memory is usually divided into two partitions: one for the resident operating system and one for the user processes.
- We can place the operating system in either low memory or high memory. The major factor affecting this decision is the location of the interrupt vector. Since the interrupt vector is often in low memory, programmers usually place the operating system in low memory as well.
- We usually want several user processes to reside in memory at the same time. We therefore need to consider how to allocate available memory to the processes that are in the input queue waiting to be brought into memory. In contiguous memory allocation, each process is contained in a single section of memory that is contiguous to the section containing the next process.

### **Memory Protection**

• Before discussing memory allocation further, we must discuss the issue of memory protection. If we have a system with a relocation register, together with a limit, we accomplish our goal. The relocation register contains the value of the smallest physical

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

address; the limit register contains the range of logical addresses (for example, relocation = 100040 and limit = 74600).

• Each logical address must fall within the range specified by the limit register. The MMU maps the logical address dynamically by adding the value in the relocation register. This mapped address is sent to memory. When the CPU scheduler selects a process for execution, the dispatcher loads the relocation and limit registers with the correct values as part of the context switch. Because every address generated by a CPU is checked against these registers, we can protect both the operating system and the other users' programs and data from being modified by this running process.

### **Memory Allocation**

- One of the simplest methods for allocating memory is to divide memory into several fixedsized **partitions**. Each partition may contain exactly one process. Thus, the degree of multiprogramming is bound by the number of partitions. In this multiple **partition method**, when a partition is free, a process is selected from the input queue and is loaded into the free partition.
- When the process terminates, the partition becomes available for another process. This
  method was originally used by the IBM OS/360 operating system (called MFT) but is no
  longer in use. The method described next is a generalization of the fixed-partition scheme
  (called MVT); it is used primarily in batch environments. Many of the ideas presented here
  are also applicable to a time-sharing environment in which pure segmentation is used for
  memory management.
- In the variable-partition scheme, the operating system keeps a table indicating which parts of memory are available and which are occupied. Initially, all memory is available for user processes and is considered one large block of available memory, a hole. Eventually, as you will see, memory contains a set of holes of various sizes.
- As processes enter the system, they are put into an input queue. The operating system takes into account the memory requirements of each process and the amount of available memory space in determining which processes are allocated memory.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- When a process is allocated space, it is loaded into memory, and it can then compete for CPU time. When a process terminates, it releases its memory, which the operating system may then fill with another process from the input queue.
- In general, the memory blocks available comprise a set of holes of various sizes scattered throughout memory. When a process arrives and needs memory, the system searches the set for a hole that is large enough for this process. If the hole is too large, it is split into two parts. One part is allocated to the arriving process; the other is returned to the set of holes. When a process terminates, it releases its block of memory, which is then placed back in the set of holes.
- If the new hole is adjacent to other holes, these adjacent holes are merged to form one larger hole. At this point, the system may need to check whether there are processes waiting for memory and whether this newly freed and recombined memory could satisfy the demands of any of these waiting processes. This procedure is a particular instance of the general dynamic storage allocation problem, which concerns how to satisfy a request of size n from a list of free holes. There are many solutions to this problem. The first-fit, best-fit, and worst-fit strategies are the ones most commonly used to select a free hole from the set of available holes.

• First fit. Allocate the first hole that is big enough. Searching can start either at the beginning of the set of holes or at the location where the previous first-fit search ended. We can stop searching as soon as we find a free hole that is large enough.

• **Best fit.** Allocate the smallest hole that is big enough. We must search the entire list, unless the list is ordered by size. This strategy produces the smallest leftover hole.

• Worst fit. Allocate the largest hole. Again, we must search the entire list, unless it is sorted by size. This strategy produces the largest leftover hole, which may be more useful than the smaller leftover hole from a best-fit approach.

#### **Fragmentation**

• Both the first-fit and best-fit strategies for memory allocation suffer from **external fragmentation.** As processes are loaded and removed from memory, the free memory space is broken into little pieces. External fragmentation exists when there is enough total memory

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

space to satisfy a request but the available spaces are not contiguous: storage is fragmented into a large number of small holes. This fragmentation problem can be severe. In the worst case, we could have a block of free (or wasted) memory between every two processes. If all these small pieces of memory were in one big free block instead, we might be able to run several more processes.

- Whether we are using the first-fit or best-fit strategy can affect the amount of fragmentation. (First fit is better for some systems, whereas best fit is better for others.) Another factor is which end of a free block is allocated. (Which is the leftover piece—the one on the top or the one on the bottom?) Memory fragmentation can be internal as well as external. Consider a multiple-partition allocation scheme with a hole of 18,464 bytes. Suppose that the next process requests 18,462 bytes. If we allocate exactly the requested block, we are left with a hole of 2 bytes. The overhead to keep track of this hole will be substantially larger than the hole itself.
- The general approach to avoiding this problem is to break the physical memory into fixedsized blocks and allocate memory in units based on block size. With this approach, the memory allocated to a process may be slightly larger than the requested memory. The difference between these two numbers is **internal fragmentation**—unused memory that is internal to a partition.
- One solution to the problem of external fragmentation is compaction. The goal is to shuffle the memory contents so as to place all free memory together in one large block. Compaction is not always possible, however. If relocation is static and is done at assembly or load time, compaction cannot be done. It is possible only if relocation is dynamic and is done at execution time. Another possible solution to the external-fragmentation problem is to permit the logical address space of the processes to be noncontiguous, thus allowing a process to be allocated physical memory wherever such memory is available. Two complementary techniques achieve this solution: segmentation and paging

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

## **PAGING**

- It is a memory-management scheme that permits the physical address space a process to be noncontiguous. Paging avoids external fragmentation and the need for compaction. It also solves the considerable problem of fitting memory chunks of varying sizes onto the backing store; most memory management schemes used before the introduction of paging suffered from this problem. The problem arises because, when some code fragments or data residing in main memory need to be swapped out, space must be framed on the backing store.
- The backing store has the same fragmentation problems discussed in connection with main memory, but access is much slower, so compaction is impossible. Because of its advantages over earlier methods, paging in its various forms is used in most operating systems.

Traditionally, support for paging has been handled by hardware. However, recent designs have implemented paging by closely integrating the hardware and operating system, especially on 64-bit microprocessors.

### **Basic Method**

- The basic method for implementing paging involves breaking physical memory into fixedsized blocks called frames and breaking logical memory into blocks of the same size called pages.
- When a process is to be executed, its pages are loaded into any available memory frames from their source (a file system or the backing store). The backing store is divided into fixed-sized blocks that are of the san1.e size as the memory frames. The hardware support for paging is illustrated in the following figure

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• Every address generated the CPU is divided into two parts: a {p) and a . The page number is used as an index into a page table contains the base address of each page in physical memory. This base address is combined with the page offset to define the physical memory address that is sent to the memory unit. The paging model of memory is shown in the following diagram

• The page size (like the frame size) is defined by the hardware. The size of a page is typically a power of 2, varying between 512 bytes and 16 MB per page, depending on the computer architecture. The selection of a power of 2 as a page size makes the translation of a logical address into a page number and page offset particularly easy.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

page number	page offset
р	d
m-n	п

• If the size of the logical address space is 2m, and a page size is 271 addressing units (bytes or wordst then the high-order m- n bits of a logical address designate the page number, and the n low-order bits designate the page offset. Thus, the logical address is as follows: where p is an index into the page table and d is the displacement within the page. As a concrete (although minuscule) example, consider the memory in the following diagram

- Here, in the logical address, n= 2 and m = 4. Using a page size of 4 bytes and a physical memory of 32 bytes (8 pages), we show how the user's view of memory can be mapped into physical memory. Logical address 0 is page 0, offset 0. Indexing into the page table, we find that page 0 is in frame 5. Thus, logical address 0 maps to physical address 20 [= (5 x 4) + 0]. Logical address 3 (page 0, offset 3) maps to physical address 23 [ = (5 x 4) + 3].
- Logical address 4 is page 1, offset 0; according to the page table, page 1 is mapped to frame
   6. Thus, logical address 4 maps to physical address 24 [ = ( 6 x 4) + O]. Logical address 13 maps to physical address 9. You may have noticed that paging itself is a form of dynamic relocation. Every logical address is bound by the paging hardware to some physical address.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

Using paging is similar to using a table of base (or relocation) registers, one for each frame of memory. When we use a paging scheme, we have no external fragmentation: any free frame can be allocated to a process that needs it. However, we may have some internal fragmentation. Notice that frames are allocated as units.

- If the memory requirements of a process do not happen to coincide with page boundaries, the last frame allocated may not be completely full. For example, if page size is 2,048 bytes, a process of 72,766 bytes will need 35 pages plus 1,086 bytes. It will be allocated 36 frames, resulting in internal fragmentation of 2,048 1,086 = 962 bytes. In the worst case, a process would need 11 pages plus 1 byte. It would be allocated 11 + 1 frames, resulting in internal fragmentation of almost an entire frame. If process size is independent of page size, we expect internal fragmentation to average one-half page per process. This consideration suggests that small page sizes are desirable. Generally, page sizes have grown over time as processes, data sets, and main memory have become larger.
- Today, pages typically are between 4 KB and 8 KB in size and some systems support even larger page sizes. Some CPUs and kernels even support multiple page sizes. For instance, Solaris uses page sizes of 8 KB and 4 MB, depending on the data stored by the pages. Researchers are now developing support for variable on-the-fly page size. Usually, each page-table entry is 4 bytes long, but that size can vary as well. A 32-bit entry can point to one of 232 physical page frames. If frame size is 4 KB, then a system with 4-byte entries can address 244 bytes (or 16 TB) of physical memory. When a process arrives in the system to be executed, its size, expressed in pages, is examined. Each page of the process needs one frame. Thus, if the process requires 11 pages, at least 11 frames must be available in memory.
- If n frames are available, they are allocated to this arriving process. The first page of the process is loaded into one of the allocated frames, and the frame number is put in the page table for this process. The next page is loaded into another frame, its frame number is put into the page table, and so on. An important aspect of paging is the clear separation between the user's view of memory and the actual physical memory. The user program views

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

memory as one single space, containing only this one program. In fact, the user program is scattered throughout physical memory, which also holds other programs.

- The difference between the user's view of memory and the actual physical memory is reconciled by the address-translation hardware. The logical addresses are translated into physical addresses. This mapping is hidden from the user and is controlled by the operating system. Notice that the user process by definition is unable to access memory it does not own.
- It has no way of addressing memory outside of its page table, and the table includes only those pages that the process owns. Since the operating system is managing physical memory, it must be aware of the allocation details of physical memory-which frames are allocated, which frames are available, how many total frames there are, and so on. This information is generally kept in a data structure called a frame the frame-table has one entry for each physical page frame, indicating whether the latter is free or allocated and, if it is allocated, to which page of which process or processes.
- In addition, the operating system must be aware that user processes operate in user space, and all logical addresses must be mapped to produce physical addresses. If a user makes a system call (to do I/0, for example) and provides an address as a parameter (a buffe1~ for instance), that address must be mapped to produce the correct physical address.
- The operating system maintains a copy of the page table for each process, just as it maintains a copy of the instruction counter and register contents. This copy is used to translate logical addresses to physical addresses whenever the operating system must map a logical address to a physical address manually. It is also used by the CPU dispatcher to define the hardware page table when a process is to be allocated the CPU. Paging therefore increases the context-switch time.

### **STRUCTURE OF PAGE TABLE**

In this section, we explore some of the most common techniques for structuring the page table, including hierarchical paging, hashed page tables, and inverted page tables.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### **Hierarchical Paging**

• Most modern computer systems support a large logical address space (232 to 264). In such an environment, the page table itself becomes excessively large. For example, consider a system with a 32-bit logical address space. If the page size in such a system is 4 KB (212), then a page table may consist of up to 1 million entries (232/212). Assuming that each entry consists of 4 bytes, each process may need up to 4 MB of physical address space for the page table alone. Clearly, we would not want to allocate the page table contiguously in main memory. One simple solution to this problem is to divide the page table into smaller pieces.

• We can accomplish this division in several ways. One way is to use a two-level paging algorithm, in which the page table itself is also paged. For example, consider again the system with a 32-bit logical address space and a page size of 4 KB. A logical address is divided into a page number

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

consisting of 20 bits and a page offset consisting of 12 bits. Because we page the page table, the page number is further divided into a 10-bit page number and a 10-bit page offset. Thus, a logical address is as follows:

Where p1 is an index into the outer page table and p2 is the displacement within the page of the inner page table. The address-translation method for this architecture is shown in Figure. Because address translation works from the outer page table inward, this scheme is also known as a forward-mapped page table.

## Hashed Page Tables

- A common approach for handling address spaces larger than 32 bits is to use a hashed page table, with the hash value being the virtual page number. Each entry in the hash table contains a linked list of elements that hash to the same location (to handle collisions). Each element consists of three fields: (1) the virtual page number, (2) the value of the mapped page frame, and (3) a pointer to the next element in the linked list. The algorithm works as follows:
- The virtual page number in the virtual address is hashed into the hash table. The virtual page number is compared with field 1 in the first element in the linked list. If there is a match, the corresponding page frame (field 2) is used to form the desired physical address. If there is no match, subsequent entries in the linked list are searched for a matching virtual page number.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

### **Inverted Page Tables**

- Usually, each process has an associated page table. The page table has one entry for each page that the process is using (or one slot for each virtual address, regardless of the latter's validity). This table representation is a natural one, since processes reference pages through the pages' virtual addresses.
- The operating system must then translate this reference into a physical memory address. Since the table is sorted by virtual address, the operating system is able to calculate where in the table the associated physical address entry is located and to use that value directly. One of the drawbacks of this method is that each page table may consist of millions of entries. These tables may consume large amounts of physical memory just to keep track of how other physical memory is being used.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• To solve this problem, we can use an inverted page table. An inverted page table has one entry for each real page (or frame) of memory. Each entry consists of the virtual address of the page stored in that real memory location, with information about the process that owns the page. Thus, only one page table is in the system, and it has only one entry for each page of physical memory.

### **Shared Pages**

• An advantage of paging is the possibility of sharing common code. This consideration is particularly important in a time-sharing environment. Consider a system that supports 40 users, each of whom executes a text editor. If the text editor consists of 150 KB of code and 50 KB of data space, we need 8,000 KB to support the 40 users. If the code is reentrant code (or pure code), it can be shared, as shown in Figure. Here, we see three processes sharing a three-page editor—each page 50 KB in size (the large page size is used to simplify the figure). Each process has its own data page. Reentrant code is non-self-modifying code: it never changes during execution. Thus, two or more processes can execute the same code at the same time.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

- Each process has its own copy of registers and data storage to hold the data for the process's execution. The data for two different processes will, of course, be different. Only one copy of the editor need be kept in physical memory. Each user's page table maps onto the same physical copy of the editor, but data pages are mapped onto different frames. Thus, to support 40 users, we need only one copy of the editor (150 KB), plus 40 copies of the 50 KB of data space per user. The total space required is now 2,150 KB instead of 8,000 KB—a significant savings. Other heavily used programs can also be shared—compilers, window systems, run-time libraries, database systems, and so on. To be sharable, the code must be reentrant. The read-only nature of shared code should not be left to the correctness of the code; the operating system should enforce this property.
- The sharing of memory among processes on a system is similar to the sharing of the address space of a task by threads.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

## **SEGMENTATION**

• An important aspect of memory management that became unavoidable with paging is the separation of the user's view of memory from the actual physical memory. As we have already seen, the user's view of memory is not the same as the actual physical memory. The user's view is mapped onto physical memory. This mapping allows differentiation between logical memory and physical memory.

### **Basic Methods**

• It is a memory-management scheme that supports this user view of memory. A logical address space is a collection of segments. Each segment has a name and a length. The addresses specify both the segment name and the offset within the segment. The user therefore specifies each address by two quantities: a segment name and an offset. (Contrast this scheme with the paging scheme, in which the user specifies only a single address, which is partitioned by the hardware into a page number and an offset, all invisible to the programmer.) For simplicity of implementation, segments are numbered and are referred to by a segn"lent number, rather than by a segment name. Thus, a logical address consists of a two tuple:

<segment-number, offset>.

- Normally, the user program is compiled, and the compiler automatically constructs segments reflecting the input program. A C compiler might create segarate segments for the following:
  - 1. The code
  - 2. Global variables
  - 3. The heap, from which memory is allocated
  - 4. The stacks used by each thread
  - 5. The standard C library
- Libraries that are linked in during compile time might be assigned separate segments. The loader would take all these segments and assign them segment numbers.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

## <u>Hardware</u>

• Although the user can now refer to objects in the program by a two-dimensional address, the actual physical memory is still, of course, a one-dimensional sequence of bytes. Thus, we must define an implementation to map two dimensional user-defined addresses into one-dimensional physical addresses. This mapping is affected by each entry in the segment table has a segment base and a segment limit. The segment base contains the start physical address where the segment resides in memory, and the segment limit specifies the length of the segment. The use of a segment table is illustrated in Figure

• A logical address consists of two parts: a segment number, s, and an offset into that segment, d. the segment number is used as an index to the segment table. The offset d of the logical address must be between 0 and the segment limit. If it is not, we trap to the operating system (logical addressing attempt beyond end of segment). When an offset is legal, it is added to the segment base to produce the address in physical memory of the desired byte. The segment table is thus essentially an array of base-limit register pairs. As an example, consider the situation shown in Figure

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

We have five segments numbered from 0 through 4. The segments are stored in physical memory as shown. The segment table has a separate entry for each segment, giving the beginning address of the segment in physical memory (or base) and the length of that segment (or limit). For example, segment 2 is 400 bytes long and begins at location 4300. Thus, a reference to byte 53 of segment 2 is mapped onto location 4300 +53= 4353. A reference to segment 3, byte 852, is mapped to 3200 (the base of segment 3) + 852 = 4052. A reference to byte 1222 of segment 0 would result in a trap to the operating system, as this segment is only 1000 bytes long.

### Segmentation and Paging

• A user program can be subdivided using segmentation, in which the program and its associated data are divided into a number of **segments.** It is not required that all segments of all programs be of the same length, although there is a maximum segment length. As with paging, a logical address using segmentation consists of two parts, in this case a

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

segment number and an offset. Because of the use of unequal-size segments, segmentation is similar to dynamic partitioning.

- In the absence of an overlay scheme or the use of virtual memory, it would be required that all of a program's segments be loaded into memory for execution. The difference, compared to dynamic partitioning, is that with segmentation a program may occupy more than one partition, and these partitions need not be contiguous. Segmentation eliminates internal fragmentation but, like dynamic partitioning, it suffers from external fragmentation.
- However, because a process is broken up into a number of smaller pieces, the external fragmentation should be less. Whereas paging is invisible to the programmer, segmentation is usually visible and is provided as a convenience for organizing programs and data. STypically, the programmer or compiler will assign programs and data to different segments. For purposes of modular programming, the program or data may be further broken down into multiple segments.
- The principal inconvenience of this service is that the programmer must be aware of the maximum segment size limitation. Another consequence of unequal-size segments is that there is no simple relationship between logical addresses and physical addresses.
- Each segment table entry would have to give the starting address in main memory of the corresponding segment. The entry should also provide the length of the segment, to assure that invalid addresses are not used. When a process enters the Running state, the address of its segment table is loaded into a special register used by the memory management hardware. Consider an address of n\_m bits, where the leftmost n bits are the segment number and the rightmost m bits are the offset. In our example (Figure C), n\_4 and m\_12. Thus the maximum segment size is 2 12 \_ 4096.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

The following steps are needed for address translation:

• Extract the segment number as the leftmost n bits of the logical address.

• Use the segment number as an index into the process segment table to find the starting physical address of the segment.

• Compare the offset, expressed in the rightmost m bits, to the length of the segment.

If the offset is greater than or equal to the length, the address is invalid. The desired physical address is the sum of the starting physical address of the segment plus the offset.

To summarize, with simple segmentation, a process is divided into a number of segments that need not be of equal size. When a process is brought in, all of its segments are loaded into available regions of memory, and a segment table is set up.

## VIRTUAL MEMORY

## Virtual Memory and its Organization

- Virtual memory is a technique that allows the execution of processes which are not completely available in memory. The main visible advantage of this scheme is that programs can be larger than physical memory. Virtual memory is the separation of user logical memory from physical memory. This separation allows an extremely large virtual memory to be provided for programmers when only a smaller physical memory is available. Following are the situations, when entire program is not required to be loaded fully in main memory.
- User written error handling routines are used only when an error occured in the data or computation.
- Certain options and features of a program may be used rarely.
- Many tables are assigned a fixed amount of address space even though only a small amount of the table is actually used.
- The ability to execute a program that is only partially in memory would counter many benefits.
- Less number of I/O would be needed to load or swap each user program into memory.
- A program would no longer be constrained by the amount of physical memory that is available.
- Each user program could take less physical memory, more programs could be run the same time, with a corresponding increase in CPU utilization and throughput.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• Virtual memory is commonly implemented by demand paging. It can also be implemented in a segmentation system. Demand segmentation can also be used to provide virtual memory.

### **Demand Paging**

- A demand paging system is quite similar to a paging system with swapping. When we want to execute a process, we swap it into memory. Rather than swapping the entire process into memory, however, we use a lazy swapper called pager.
- When a process is to be swapped in, the pager, guesses which pages will be used before the process is swapped out again. Instead of swapping in a whole process, the pager brings only those necessary pages into memory. Thus, it avoids reading into memory pages that will not be used in anyway, decreasing the swap time and the amount of physical memory needed.
- Hardware support is required to distinguish between those pages that are in memory and those pages that are on the disk using the valid-invalid bit scheme, where valid and invalid pages can be checked by checking the bit. Marking a page will have no effect if the process never attempts to access the page. While the process executes and accesses pages that are memory resident, execution proceeds normally.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

• Access to a page marked invalid causes a page-fault trap. This trap is the result of the operating system's failure to bring the desired page into memory. But page fault can be handled as following

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

Step	Description
Step 1	Check an internal table for this process, to determine whether the reference was a valid or it was an invalid memory access.
Step 2	If the reference was invalid, terminate the process. If it was valid, but page have not yet brought in, page in the latter.
Step 3	Find a free frame.
Step 4	Schedule a disk operation to read the desired page into the newly allocated frame.
Step 5	When the disk read is complete, modify the internal table kept with the process and the page table to indicate that the page is now in memory.
Step 6	Restart the instruction that was interrupted by the illegal address trap. The process can now access the page as though it had always been in memory. Therefore, the operating system reads the desired page into memory and restarts the process as though the page had always been in memory.

### > Advantages

Following are the advantages of Demand Paging

- Large virtual memory.
- More efficient use of memory.
- Unconstrained multiprogramming. There is no limit on degree of multiprogramming.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

## > Disadvantages

Following are the disadvantages of Demand Paging

- Number of tables and amount of processor overhead for handling page interrupts are greater than in the case of the simple paged management techniques.
- Due to the lack of an explicit constraint on a job address space size.

CLASS: II BCA COURSE CODE: 16CAU601B COURSE NAME: UNIX/LINUX PROGRAMMING UNIT - III BATCH: 2016 – 2019

## POSSIBLE QUESTIONS UNIT – III PART – A (20 MARKS) (Q.NO 1 TO 20 Online Examinations)

## PART – B (2 MARKS)

- 1. What do you mean by granting right?
- 2. What is user management commands?
- 3. What is File Quota?
- 4. Define File Layout.
- 5. What do you mean by managing disk quotas?
- 6. Define symbolic link.

### PART – C (6 MARKS)

- 1. Explain the types of users.
- 2. Explain the user management commands.
- 3. Explain the file quota and various file systems available.
- 4. Discuss the file system management and layout.
- 5. Explain the file permissions.
- 6. Discuss the login process.

**Coimbatore – 641 021.** 

(For the Candidates admitted from 2016 onwards)

### UNIT V

System calls, Using system calls Pipes and Filters, Decision making in Shell Scripts (If else, switch), Loops in shell, Functions, Utility programs (cut, paste, join, tr, uniq utilities), Pattern matching utility (grep)

Linux looks and feels much like any other UNIX system. Its development began in 1991, when a Finnish student, Linus Torvalds, wrote and christened Linux, a small but self-contained kernel for the 80386 processor, the first true 32-bit processor in Intel's range of PC-compatible CPUs. From an initial kernel that partially implemented a small subset of the UNIX system services, the Linux system has grown to include much ifFNIX functionality. In its early days, Linux development revolved largely around the central operating-system kernel—the core, privileged executive that manages all system resources and that interacts directly with the computer hardware. The Linux kernel is an entirely original piece of software developed from scratch by the Linux community. The Linux system, as we know it today, includes a multitude of components, some written from scratch, others borrowed from other development projects, and still others created in collaboration with other teams. A Linux distribution includes all the standard components of the Linux system, plus a set of administrative tools to simplify the initial installation and subsequent upgrading of Linux and to manage installation and removal of other packages on the system.

#### **1.2 The Linux Kernel**

The first Linux kernel released to the public was Version 0.01, dated May 14, 1991. It had no networking, ran only on 80386-compatible Intel processors and PC hardware, and had extremely limited device-driver support. The virtual memory subsystem was also fairly basic and included no support for memory mapped files; however, even this early incarnation supported shared pages with copy-on-write. The only file system supported was the Minix file system -the first Linux kernels were cross-developed on a Minix platform.

The next milestone version, Linux 1.0, was released on March 14, 1994. This release culminated three years of rapid development of the LimIX kernel. Perhaps the single biggest new feature was networking: 1.0 included support for UNIX's standard

TCP liP networking protocols, as well as a BSD-compatible socket interface for networking programming. Device-driver support was added for running IP over an Ethernet or (using PPP or SLIP protocols) over serial lines or modems. The 1.0 kernel also included a new, much enhanced file system without the limitations of the original Minix file system and supported a range of SCSI controllers for high-performance disk access. The developers extended the virtual memory subsystem to support paging to swap files and memory mapping of arbitrary files (but only read-only memory mapping was implemented in 1.0). A range of extra hardware support was also included in this release.

Although still restricted to the Intel PC platform, hardware support had grown to include floppy-disk and CD-ROM devices, as well as sound cards, a range of mice, and international keyboards. Floating-point emulation was provided in the kernel for 80386 users who had no 80387 math coprocessor; System V UNIX-style inclLlding shared memory, semaphores, and message queues, was implemented. Simple support for dynamically loadable and unloadable kernel modules was supplied as well. At this point, development started on the 1.1 kernel stream, but numerous bug-fix patches were released subsequently against 1.0.

In March 1995, the 1.2 kernel was released. This release did not offer nearly the same improvement in functionality as the 1.0 release, but it did support a much wider variety of hardware, including the new PCI hardware bus architecture. Developers added another PC-specific feature-support for the 80386 CPU's virtual8086 mode-to allow emulation of the DOS operating system for PC computers. They also updated the networking stack to provide support for the IPX protocol and made the IP implementation more complete by including accounting and firewalling functionality.

The 1.2 kernel was the final PC-only Linux kernel. The source distribution for Linux 1.2 included partially implemented support for SPARC, Alpha, and MIPS CPUs, but full integration of these other architectures did not begin until after the 1.2 stable kernels was released. The Linux 1.2 release concentrated on wider hardware support and more complete implementations of existing functionality.

Much new functionality was under development at the time, but integration of the new code into the main kernel source code had been deferred until after the stable 1.2 kernel had been released. As a result, the 1.3 development stream saw a great deal of new

functionality added to the kernel. This work was finally released as Linux 2.0 in since 1996. This release was given a major version-number increment on account of two major new capabilities: support for multiple architectures, including a 64-bit native Alpha port, and support for multiprocessor architectures. Linux distributions based on 2.0 are also available for the Motorola 68000-series processors and for Sun's SPARC systems.

A derived version of Linux running on top of the Mach microkernel also runs on PC and PowerMac systems. The changes in 2.0 did not stop there. The memorymanagement code was substantially improved to provide a unified cache for file-system data independent of the caching of block devices. As a result of this change, the kernel offered greatly increased file-system and virtual memory performance. For the first time, file-system caching was extended to networked file systems, and writable memorymapped regions also were supported. The 2.0 kernel also included much improved TCP /IP performance, and a number of new networking protocols were added, including Apple

Talk, AX.25an'lateur radio networking, and ISDN support. The ability to mount remote netware and SMB (Microsoft LanManager) network volumes was added. Other major improvements in 2.0 were support for internal kernel threads, for handling dependencies between loadable modules, and for automatic loading of modules on demand. Dynamic configuration of the kernel at run time was much improved through a new, standardized configuration interface. Additional new features included file-system quotas and POSIX-compatible real-time process-scheduling classes. Improvements continued with the release of Linux 2.2 in January 1999.

A port for UltraSPARC systems was added. Networking was enhanced with more flexible firewalling, better routing and traffic management, and support for TCP large window and selective acks. Acorn, Apple, and NT disks could now be read, and NFS was enhanced and a kernel-mode NFS daemon added. Signal handling, interrupts, and some I/0 were locked at a finer level than before to improve symmetric multiprocessor (SMP) performance. Advances in the 2.4 and 2.6 releases of the kernel include increased support for SMP systems, journaling file systems, and enhancements to the memory management system. The process scheduler was modified in Version 2.6, providing an efficient 0(1) scheduling algorithm. In addition, the LimiX 2.6 kernel is now preemptive, allowing a process to be preempted while running in kernel mode.

### 1.3 The Linux System: Design Principles

- Linux is a multiuser, multitasking system with a full set of UNIX-compatible tools.
- Its file system adheres to traditional UNIX semantics, and it fully implements the standard UNIX networking model.
- Main design goals are speed, efficiency, flexibility and standardization.
- Linux is designed to be compliant with the relevant POSIX documents; some Linux distributions have achieved official POSIX certification.
- The Linux programming interface adheres to the SVR4 UNIX semantics, rather than to BSD behavior.

### 1.4 The layers of a UNIX system

### 1.5 Components of a UNIX System

- Like most UNIX implementations, Linux is composed of three main bodies of code:
  - Standard Utilities Programs
  - Standard Library
  - ➤ Kernel
- Standard Utilities Programs perform individual specialized management tasks.
  - ➤ Shell

- Commands for the management of files and directories
- ➢ Filters
- ➢ Compilers
- ➢ Editors
- > Commands for the administration of the system

### 1.6 The shell of a UNIX System

- The UNIX systems have a Graphical User Interface (Linux uses KDE, GNOME ...), but the programmers prefer to type the commands.
- Shell: the user process which executes programs (command interpreter)
  - ➢ User types command
  - Shell reads command (read from input) and translates it to the operating system.
- Can run external programs (e.g. netscape) or internal shell commands (e.g. cd)
- Various different shells available:
  - Bourne shell (sh), C shell (csh), Korn shell (ksh), TC shell (tcsh), Bourne Again shell (bash).
- The administrator of the system provides to the user a default shell, but the user can change shell.

### **1.7 Memory Management**

Memory management under Linux has two components. The first deals with allocating and freeing physical memory—pages, groups of pages, and small blocks of memory. The second handles virtual memory, which is memory mapped into the address space of running processes.

### Management of Physical Memory

Due to specific hardware characteristics, Linux separates physical memory into three different zones identifying different regions of memory. The zones are identified as:

- ZONE\_DMA
- ZONEJTORMAL
- ZONE\_HIGHMEM

These zones are architecture specific. For example, on the Intel 80x86 architecture, certain ISA (industry standard architecture) devices can only access the

lower 16 MB of physical memory using DMA. On these systems, the first 16 MB of physical memory comprise ZONE-DMA. ZQNEJIORMAL identifies physical memory that is mapped to the CPU's address space. This zone is used for most routine memory requests. For architectures that do not limit what DMA can access, ZONEJDMA is not present, and ZQNEJJQRMAL is used.

Finally, ZONE\_HIGHMEM (for "high memory") refers to physical memory that is not mapped into the kernel address space. For example, on the 32-bit Intel architecture (where 232 provides a 4-GB address space), the kernel is mapped into the first 896 MB of the address space; the remaining memory is referred to as high memory and is allocated from ZONE\_HIGHMEM.

### **1.7 File Systems**

Linux retains UNIX's standard file-system model. In UNIX, a file does not have to be an object stored on disk or fetched over a network from a remote file server. Rather, UNIX files can be anything capable of handling the input or output of a stream of data. Device drivers can appear as files, and inter process communication channels or network connections also look like files to the user. The Linux kernel handles all these types of file by hiding the implementation details of any single file type behind a layer of software, the virtual file system (VFS). Here, we first cover the virtual file system and then discuss the standard Linux file system—ext2fs.

### The Virtual File System

The Linux VFS is designed around object-oriented principles. It has two components: a set of definitions that specify what file-system objects are allowed to look like and a layer of software to manipulate the objects. The VFS defines four main object types:

- An inode object represents an individual file.
- A file object represents an open file.
- A superblock object represents an entire file system.
- A dentry object represents an individual directory entry.

For each of these four object types, the VFS defines a set of operations. Every object of one of these types contains a pointer to a function table. The function table lists the addresses of the actual functions that implement the defined operations for that object. For example, an abbreviated API for some of the file object's operations includes:

- int open (. . .) Open a file.
- ssize t read(...) —Read from a file.
- ssize\_t write (. . .) —Write to a file.
- int mmap (...) Memory-map a file.

The complete definition of the file object is specified in the struct file\_operations, which is located in the file /usr/include/linux/fs.h. An implementation of the file object (for a specific file type) is required to implement each function specified in the definition of the file object.

The VFS software layer can perform an operation on one of the file-system objects by calling the appropriate function from the object's function table, without having to know in advance exactly what kind of object it is dealing with. The VFS does not know, or care, whether an inode represents a networked file, a disk file, a network socket, or a directory file. The appropriate function for that file's readQ operation will always be at the same place in its function table, and the VFS software layer will call that function without caring how the data are actually read.

The inode and file objects are the mechanisms used to access files. An inode object is a data structure containing pointers to the disk blocks that contain the actual hie contents, and a file object represents a point of access to the data in an open file. A process cannot access an inode's contents without first obtaining a file object pointing to the inode. The file object keeps track of where in the file the process is currently reading or writing, to keep track of sequential file I/O.

It also remembers whether the process asked for write permissions when the file was opened and tracks the process's activity if necessary to perform adaptive read-ahead, fetching file data into memory before the process requests the data, to improve performance. File objects typically belong to a single process, but inode objects do not.

Even when a file is no longer being used by any processes, its inode object may still be cached by the VFS to improve performance if the file is used again in the near future. All cached file data are linked onto a list in the file's inode object. The inode also maintains standard information about each file, such as the owner, size, and time most recently modified.

Directory files are dealt with slightly differently from other files. The UNIX programming interface defines a number of operations on directories, such as creating, deleting, and renaming a file in a directory.

The system calls for these directory operations do not require that the user open the files concerned, unlike the case for reading or writing data. The VFS therefore defines these directory operations in the inode object, rather than in the file object. The superblock object represents a connected set of files that form a self-contained file system. The operating-system kernel maintains a single superblock object for each disk device mounted as a file system and for each networked file system currently connected.

The main responsibility of the superblock object is to provide access to inodes. The VFS identifies every inode by a unique (file-system/inode number) pair, and it finds the inode corresponding to a particular inode number by asking the superblock object to return the inode with that number.

Finally, a dentry object represents a directory entry that may include the name of a directory in the path name of a file (such as /usr) or the actual file (such as s t d i o . h). For example, the file Aisr/include/stdio. h contains the directory entries (1) /, (2) usr, (3) include, and (4) stdio .h. Each one of these values is represented by a separate dentry object.

As an example of how dentry objects are used, consider the situation in which a process wishes to open the file with the pathname /  $u \le r / i \le l \le d \le s \le d \le o$ . In using an editor. Because Linux treats directory names as files, translating this path requires first obtaining the inode for the root /. The operating system must then read through this file to obtain the inode for the file include. It must continue this process until it obtains the inode for the file s t d io . h. Because path-name translation can be a time-consuming task, Linux maintains a cache of dentry objects, which is consulted during path-name translation. Obtaining the inode from the dentry cache is considerably faster than having to read the on-disk file.

#### The Linux ext2fs File System

The standard on-disk file system used by Linux is called **ext2fs**, for historical reasons. Linux was originally programmed with a Minix-compatible filesystem, to ease exchanging data with the Minix development system, but that file system was severely restricted by 14-character file-name limits and a maximum file-system size of 64 MB. The Minix file system was superseded by a new file system, which was christened the **extended file system (extfs).** A later redesign of this file system to improve performance and scalability and to add a few missing features led to the **second extended file system** (**ext2fs)**.

#### 2. Windows 2000

**Windows 2000** is an operating system for use on both client and servercomputers. It was produced by Microsoft and released to manufacturing on December 15, 1999 and launched to retail on February 17, 2000. It is the successor to Windows NT 4.0, and is the last version of Microsoft Windows to display the "Windows NT" designation.<sup>[7]</sup> It is succeeded by Windows XP (released in October 2001) and Windows Server 2003 (released in April 2003). During development, Windows 2000 was known as Windows NT 5.0.

Four editions of Windows 2000 were released: Professional, Server, Advanced Server, and Datacenter Server; the latter was both released to manufacturing and launched months after the other editions.

While each edition of Windows 2000 was targeted at a different market, they shared a core set of features, including many system utilities such as the Microsoft Management Console and standard system administration applications.

Support for people with disabilities was improved over Windows NT 4.0 with a number of new assistive technologies, and Microsoft increased support for different languages and locale information.

#### 2.1 The Windows 2000 File System

Windows 2000 supports several file systems, the most important of which are FAT-16, FAT-32, and NTFS. This sample chapter examines the NTFS file system because it is a modern file system unencumbered by the need to be fully compatible with the MS-DOS file system. Windows 2000 supports several file systems, the most important of which are FAT-16, FAT-32, andNTFS (NT File System). FAT-16 is the old MS-DOS file system. It uses 16-bit disk addresses, which limits it to disk partitions no larger than 2 GB. FAT-32 uses 32-bit disk addresses and supports disk partitions up to 2 TB. NTFS is a new file system developed specifically for Windows NT and carried over to Windows 2000. It uses 64-bit disk addresses and can (theoretically) support disk partitions up to  $2^{64}$  bytes, although other considerations limit it to smaller sizes. Windows 2000 also supports read-only file systems for CD-ROMs and DVDs. It is possible (even common) to have the same running system have access to multiple file system types available at the same time.

#### **Fundamental Concepts**

Individual file names in NTFS are limited to 255 characters; full paths are limited to 32,767 characters. File names are in Unicode, allowing people in countries not using the Latin alphabet (e.g., Greece, Japan, India, Russia, and Israel) to write file names in their native language. For example, file is a perfectly legal file name. NTFS fully supports case sensitive names (so foo is different from Foo andFOO). Unfortunately, the Win32 API does not fully support case-sensitivity for file names and not at all for directory names, so this advantage is lost to programs restricted to using Win32 (e.g., for Windows 98 compatibility).

An NTFS file is not just a linear sequence of bytes, as FAT-32 and UNIX files are. Instead, a file consists of multiple attributes, each of which is represented by a stream of bytes. Most files have a few short streams, such as the name of the file and its 64-bit object ID, plus one long (unnamed) stream with the data. However, a file can also have two or more (long) data streams as well. Each stream has a name consisting of the file name, a colon, and the stream name, as in foo:stream1. Each stream has its own size and is lockable independently of all the other streams. The idea of multiple streams in a file was borrowed from the Apple Macintosh, in which files have two streams, the data fork and the resource fork. This concept was incorporated into NTFS to allow an NTFS server be able to serve Macintosh clients.

File streams can be used for purposes other than Macintosh compatibility. For example, a photo editing program could use the unnamed stream for the main image and a named stream for a small thumbnail version. This scheme is simpler than the traditional way of putting them in the same file one after another. Another use of streams is in word processing. These programs often make two versions of a document, a temporary one for use during editing and a final one when the user is done. By making the temporary one a named stream and the final one the unnamed stream, both versions automatically share a file name, security information, timestamps, etc. with no extra work.

The maximum stream length is  $2^{64}$  bytes. To get some idea of how big a  $2^{64}$ -byte stream is, imagine that the stream were written out in binary, with each of the 0s and 1s in each byte occupying 1 mm of space. The  $2^{67}$ -mm listing would be 15 light-years long, reaching far beyond the solar system, to Alpha Centauri and back. File pointers are used to keep track of where a process is in each stream, and these are 64 bits wide to handle the maximum length stream, which is about 18.4 exabytes.

The Win32 API function calls for file and directory manipulation are roughly similar to their UNIX counterparts, except most have more parameters and the security model is different. Opening a file returns a handle, which is then used for reading and writing the file. For graphical applications, no file handles are predefined. Standard input, standard output, and standard error have to be acquired explicitly if needed; in console mode they are preopened, however. Win32 also has a number of additional calls not present in UNIX.

#### 3. Windows XP

The Microsoft Windows XP operating system is a 32/64-bit preemptive multitasking operating system for AMD K6/K7, Intel IA32/IA64, and later microprocessors. The successor to Windows NT and Windows 2000, Windows XP is also intended to replace the Windows 95/98 operating system. Key goals for the system are security, reliability, ease of use, Windows and POSIX application compatibility, high performance, extensibility, portability, and international support.

### 3.1 History

In the mid-1980s, Microsoft and IBM cooperated to develop the OS/2 operating system, which was written in assembly language for single-processor Intel 80286 systems. In 1988, Microsoft decided to make a fresh start and to develop a "new technology" (or NT) portable operating system that supported both the OS/2 and POSIX application-programming interfaces (APIs). In October 1988, Dave Cutler, the architect of the DEC VAX/VMS operating system, was hired and given the charter of building this new operating system. Originally, the team planned for NT to use the OS/2 API as its native environment, but during development, NT was changed to use the 32-bit Windows API (or Win32 API), reflecting the popularity of Windows 3.0.

The first versions of NT were Windows NT 3.1 and Windows NT 3.1 Advanced Server. (At that time, 16-bit Windows was at version 3.1.) Windows NT version 4.0 adopted the Windows 95 user interface and incorporated Internet web-server and webbrowser software. In addition, user-interface routines and all graphics code were moved into the kernel to improve performance, with the side effect of decreased system reliability. Although previous versions of NT had been ported to other microprocessor architectures, the Windows 2000 version, released in February 2000, discontinued support for other than Intel (and compatible) processors due to marketplace factors. Windows 2000 incorporated significant changes over Windows NT. It added Active Directory (an X.500-based directory service), better networking and laptop support, support for plug-and-play devices, a distributed file system, and support for more processors and more memory.

In October 2001, Windows XP was released as both an update to the Windows 2000 desktop operating system and a replacement for Windows 95/98. In 2002, the server versions of Windows XP became available (called Windows .Net Server). Windows XP updates the graphical user interface (GUI) with a visual design that takes advantage of more recent hardware advances and many new ease-of-use features. Numerous features have been added to automatically repair problems in applications and the operating system itself. Windows XP provides better networking and device experience (including zero-configuration wireless, instant messaging, streaming media, and digital photography/video), dramatic performance improvements both for the desktop and large multiprocessors, and better reliability and security than even Windows 2000.

Windows XP uses a client-server architecture (like Mach) to implement multiple operating-system personalities, such as Win32 API and POSIX, with user-level processes called subsystems. The subsystem architecture allows enhancements to be made to one operating-system personality without affecting the application compatibility of any others.

Windows XP is a multiuser operating system, supporting simultaneous access through distributed services or through multiple instances of the graphical user interface via the Windows terminal server. The server versions of Windows XP support simultaneous terminal server sessions from Windows desktop systems. The desktop versions of terminal server multiplex the keyboard, mouse, and monitor between virtual terminal sessions for each logged-on user. This feature, called fast user switching, allows users to preempt each other at the console of a PC without having to log off and onto the system.

Windows XP is the first version of Windows to ship a 64-bit version. The native NT file system (NTPS) and many of the Win32 APIs have always used 64- bit integers where appropriate—so the major extension to 64-bit in Windows XP is support for large addresses.

There are two desktop versions of Windows XP. Windows XP Professional is the premium desktop system for power users at work and at home. For home users migrating from Windows 95/98, Window's XP Personal provides the reliability and ease of use of Windows XP, but lacks the more advanced features needed to work seamlessly with Active Directory or rim POSIX applications. The members of the Windows .Net Server family use the same core components as the desktop versions but add a range of features needed for uses such as webserver farms, print/file servers, clustered systems, and, large datacenter machines. The large datacenter machines can have up to 64 GB of memory and 32 processors on IA32 systems and 128 GB and 64 processors on IA64 systems.

### 3.1 Design Principles

Microsoft's design goals for Windows XP include security, reliability, Windows and POSIX application compatibility, high performance, extensibility, portability, and international support.

### Security

Windows XP **security** goals required more than just adherence to the design standards that enabled Windows NT 4.0 to receive a C-2 security classification from the U.S. government (which signifies a moderate level of protection from defective software and malicious attacks). Extensive code review and testing were combined with sophisticated automatic analysis tools to identify and investigate potential defects that might represent security vulnerabilities.

### Reliability

Windows 2000 was the most reliable, stable operating system Microsoft had ever shipped to that point. Much of this reliability came from maturity in the source code, extensive stress testing of the system, and automatic detection of many serious errors in drivers. The **reliability** requirements for Windows XP were even more stringent.
Microsoft used extensive manual and automatic code review to identify over 63,000 lines in the source files that might contain issues not detected by testing and then set about reviewing each area to verify that the code was indeed correct.

Windows XP extends driver verification to catch more subtle bugs, improves the facilities for catching programming errors in user-level code, and subjects third-party applications, drivers, and devices to a rigorous certification process. Furthermore, Windows XP adds new facilities for monitoring the health of the PC, including downloading fixes for problems before they are encountered by users. The perceived reliability of Windows XP was also improved by making the graphical user interface easier to use through better visual design, simpler menus, and measured improvements in the ease with which users can discover how to perform common tasks.

#### Windows and POSIX Application Compatibility

Windows XP is not only an update of Windows 2000; it is a replacement for Windows 95/98. Windows 2000 focused primarily on compatibility for business applications. The requirements for Windows XP include a much higher compatibility with consumer applications that run on Windows 95/98. **Application compatibility** is difficult to achieve because each application checks for a particular version of Windows, may have some dependence on the quirks of the implementation of APIs, may have latent application bugs that were masked in the previous system, and so forth. Windows XP introduces a compatibility layer that falls between applications and the Win32 APIs. This layer makes Windows XP look (almost) bug-for-bug compatible with previous versions of Windows.

Windows XP, like earlier NT releases, maintains support for running many 16-bit applications using a thunking, or conversion, layer that translates 16-bit API calls into equivalent 32-bit calls. Similarly, the 64-bit version of Windows XP provides a thunking layer that translates 32-bit API calls into native 64-bit calls. POSIX support in Windows XP is much improved. A new POSIX subsystem called Interix is now available. Most available UNIX-compatible software compiles and runs under Interix without modification.

#### **High Performance**

Windows XP is designed to provide **high performance** on desktop systems (which are largely constrained by I/O performance), server systems (where the CPU is often the bottleneck), and large multithreaded and multiprocessor environments (where locking and cache-line management are key to scalability).

High performance has been an increasingly important goal for Windows XP. Windows 2000 with SQL 2000 on Compaq hardware achieved top TPC-C numbers at the time it shipped. To satisfy performance requirements, NT uses a variety of techniques, such as asynchronous I/O, optimized protocols for networks (for example, optimistic locking of distributed data, batching of requests), kernel-based graphics, and sophisticated caching of file-system data.

The memory-management and synchronization algorithms are designed with an awareness of the performance considerations related to cache lines and multiprocessors. Windows XP has further improved performance by reducing the code-path length in critical functions, using better algorithms and per-processor data structures, using memory coloring for NUMA (non-uniform memory access) machines, and implementing more scalable locking protocols, such as queued spinlocks. The new locking protocols help reduce system bus cycles and include lock-free lists and queues, use of atomic read-modify-write operations (like interlocked increment), and other advanced locking techniques.

#### Extensibility

**Extensibility** refers to the capacity of an operating system to keep up with advances in computing technology. So that changes over time are facilitated, the developers implemented Windows XP using a layered architecture. The Windows XP executive runs in kernel or protected mode and provides the basic system services. On top of the executive, several server subsystems operate in user mode.

Among them are **environmental subsystems** that emulate different operating systems. Thus, programs written for MS-DOS, Microsoft Windows, and POSIX all run on Windows XP in the appropriate environment.

Because of the modular structure, additional environmental subsystems can be added without affecting the executive. In addition, Windows XP uses loadable drivers in the I/O system, so new file systems, new kinds of I/O devices, and new kinds of networking can be added while the system is running. Windows XP uses a client-server model like the Mach operating system and supports distributed processing by remote procedure calls (RPCs) as defined by the Open Software Foundation.

#### **Portability**

An operating system is **portable** if it can be moved from one hardware architecture to another with relatively few changes. Windows XP is designed to be portable. As is true of the UNIX operating system, the majority of the system is written in C and C++. Most processor-dependent code is isolated in a dynamic link library (DLL) called the **hardware-abstraction layer (HAL).** A DLL is a file that is mapped into a process's address space such that any functions in the DLL appear to be part of the process.

#### 3.2 File System

Historically, MS-DOS systems have used the file-allocation table (FAT) file system. The 16-bit FAT file system has several shortcomings, including internal fragmentation, a size limitation of 2 GB, and a lack of access protection for files. The 32bit FAT file system has solved the size and fragmentation problems, but its performance and features are still weak by comparison with modern file systems. The NTFS file system is much better. It was designed to include many features, including data recovery, security, fault tolerance, large files and file systems, multiple data streams, UNICODE names, sparse files, encryption, journaling, volume shadow copies, and file compression. Windows XP uses NTFS as its basic file system, and we focus on it here. Windows XP continues to use FAT16, however, to read floppies and other removable media. And despite the advantages of NTFS, FAT32 continues to be important for interoperability of media with Windows 95/98 systems. Windows XP supports additional file-system types for the common formats used for CD and DVD media.

## POSSIBLE QUESTIONS UNIT – V PART – A (20 MARKS) (Q.NO 1 TO 20 Online Examinations)

### PART – B (2 MARKS)

- 1. What do you mean by system calls?
- 2. What are pipes?
- 3. What are filters?
- 4. What is decision making in shell script?.
- 5. What are utility programs?

#### PART – C (6 MARKS)

- 1. Discuss the system calls.
- 2. Explain the pipes and filters.
- 3. Explain the decision making in shell script.
- 4. Discuss the utility programs of Unix and Linux.
- 5. Explain the pattern matching utility.

UNIX / LINUX PROGRAMMING

**Time: 2 Hours** Maximum: 50 Marks Date: 17-12-2018 FN

#### Part - A (20 x 1 = 20 Marks) (Answer all the Questions)

1. Unix was invented in a. Bell Laboratories b. Kell Labs c. Data Labs d. Dell Labs is the core of the operating system. Unix

- b.Kernel d. Kornel c.Knot .a. Karne is the distributor of Linux.
- a. White Hat b. Grey Hat c. Data Hat d. Red Hat
- 4. Who invented Linux operating system?. b.Linus Torvalds c. Quin Tom d. Unis Torvalds
- a. Lin Lee commands are built-in commands in Linux Shell.
- 5. a External b.File c. Data d. Internal
- command is used to check the given command is internal or 6.
- external. d. print c. echo b. cat Commands aren't built into the shell. a. type
- 7. d. grep c. cat b. External a. Error
- 8. Users typically interact with a Unix shell using a a simulator b. terminal emulator c. software emulator d.kernel standard for networking.
- d. TCP/IP 9. UNIX supports c. P2P b. HTTP in UNIX .
- 10. Persistent system service processes called\_ a. UDP d. Error c. daemons b. Exact
- a. Early system. d. NTFS File 11. UNIX supports c. Fat file a virtual file b. pseudo file

12. Linux supports GUI using System a. Y Windows b.X Windows c. MS Windows d Lindows 13. Linux is an \_\_\_\_\_\_ operating system,
 a. open windows b. open Data c. open source d.Open command
 \_\_\_\_\_\_ operating system is vulnerable to different types of attacks.
 a. UNIX b. LINUX c. Lindows d. Windows
 IS. The advantage of using Linux instead of Windows is
 a interface h user friendly c. C. Statements d. discountered 13. Linux is an a. interface b. user friendly c. customization 16. \_\_\_\_\_a Install \_\_\_\_\_Unix command is used to copy files and set file permissions. II b. Rollback c. Transform d. Refresh d. close source 17.Users communicate with the kernel through a \_\_\_\_\_ program. a.Shell b. Kernel c.Shernet d. Vernel 18. unix command is used to get information about yourself. a.user b. whoami c. userinfo d loginuser programs give user most of the functionalities of OS. 19. Linux a.user b.utility c.system dikernet feature supports users to work on different types of hardway 20. Linux a.portability b.open source c.multi user d multi tasking

#### Part - B (3 1 2=6 Marks) (Answer all the Questions)

21. What is booting? 22.Define kernel in Linux. 23 Define shell in Unix.

> Part - C (3 x 8=24 Maris) (Answer all the Questions)

24.(a) Explain the difference between Unix and Linux (OR) (b) Discuss the architecture of Unix. 25.(a) Explain the architecture of Linux.

(OR) (b) Discuss the various distributions of Units and Line

26 (a) Explain the internal and external co

(b) Explain the installation, Boot
