

### KARPAGAM ACADEMY OF HIGHER EDUCATION (Deemed to be University) (Established Under Section 3 of UGC Act, 1956) Coimbatore-21

# LECTURE PLAN

# MATHEMATICS

### SUBJECT NAME: COMPUTER GRAPHICS

**SEMESTER: V** 

# SUBJECT CODE: 16MMU503B CLASS: III B.Sc MATHEMATICS

- **Scope**: The scope of this course is to provide students with distinguished knowledge in the field of two- and three-dimensional computer graphics for Animation
- **Objectives :** To transfer to the students the skills required for designing and implementing practical graphic solutions to challenging problems in different application domains and make them a competent product.

### UNIT I

A Survey of Computer Graphics - Video Display Devices - Refresh Cathode Ray Tubes -Raster Scan Displays - Random Scan Displays - Color CRT Monitors - Direct –View Storage Tubes -Flat Panel Displays - Three Dimensional Viewing Devices – Raster Scan and Random Scan graphic storages Displays processors and Character generators, color display techniques

### UNIT II

Input Devices: Keyboards - Mouse – Track Ball and Space ball – Joysticks - Data Glove – Digitizers - Image Scanners - Touch Panels - Light Pens - Voice Systems. Hard Copy Devices: Printers and Plotters, Interactive input/output devices

Point, lines and Curves : Scan conversion, Line Drawing Algorithms: DDA Algorithm -Bresenhams Line Algorithm. Circle Generating Algorithms: Mid Point Circle Algorithm, Ellipse Generating Algorithm, Conic-section generation, polygon filling anti aliasing.

### UNIT III

Two Dimensional Geometric Transformations: Basic Transformations: Translation –Rotation – Scaling - Composite Transformations: Translations – Rotations - Scalings. General Pivot Point Rotation - General Fixed Point Scaling. Two – Dimensional Viewing: The Viewing Pipeline -Window to viewport Transformation - Clipping Operations: Point Clipping - Line Clipping Algorithms- Cohen Sutherland Line Clipping - Polygon Clipping: Sutherland – Hodgeman Polygon Clipping Algorithm - Text Clipping.

### UNIT IV

Three – Dimensional Display methods, Three – Dimensional Transformations : Translation – Rotation – Scaling, Three Dimensional viewing : Viewing pipeline - Viewing coordinates - Parallel Projection – . Perspective Projections.

### UNIT V

Visible Surface Detection Methods: Classification of Visible Surface Detection Algorithms -Back Face Detection - Depth Buffer Method - Area Sub division Method.

Computer Animation : Design of Animation Sequences-General Computer Animation functions – Raster Animations – Computer animation Languages – Key Frame Systems – Motion Specifications

### **TEXT BOOK**

1. Donald Hearn and M. Pauline Baker, (2010).Computer Graphics - C Version, Second Edition, Pearson Education, New Delhi.

A Survey of Computer Graphics - Video Display Devices - Refresh Cathode Ray Tubes -Raster Scan Displays - Random Scan Displays - Color CRT Monitors - Direct – View Storage Tubes - Flat Panel Displays - Three Dimensional Viewing Devices – Raster Scan and Random Scan graphic storages Displays processors and Character generators, color display techniques

### INTRODUCTION

Computer Graphics is the discipline of producing picture or images using a computer which include modeling, creation, manipulation, storage of geometric objects, rendering, converting a scene to an image, the process of transformations, rasterization, shading, illumination, animation of the image, etc.

Computer Graphics has been widely used in graphics presentation, paint systems, computer-aided design (CAD), image processing, simulation, etc. From the earliest text character images of a non-graphic mainframe computers to the latest photographic quality images of a high resolution personal computers, from vector displays to raster displays, from 2D input, to 3D input and beyond, computer graphics has gone through its short, rapid changing history.

From games to virtual reality, to 3D active desktops, from unobtrusive immersive home environments, to scientific and business, computer graphics technology has touched almost every concern of our life. Before we get into the details, we have a short tour through the history of computer graphics

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

# A SURVEY OF COMPUTER GRAPHICS

Computers have become a powerful tool for the rapid and economical production of pictures. There is virtually no area in which graphical displays cannot be used to some advantage, and so it is not surprising to find the use of computer graphics so widespread.

Although early applications in engineering and science had to rely on expensive and cumbersome equipment, advances in computer technology have made interactive computer graphics a practical tool. Today, we find computer graphics used routinely in such diverse areas as science, engineering, medicine, business, industry, government, art, entertainment, advertising, education, and training.

# **COMPUTER-AIDED DESIGN**

A major use of computer graphics is in design processes, particularly for engineering and architectural systems, but almost all products are now computer designed. Generally referred to as CAD, computer-aided design methods are now routinely used in the design of buildings, automobiles, aircraft, watercraft, spacecraft, computers, textiles, and many, many other products.

Software packages for CAD applications typically provide the designer with a multi-window environment. Circuits such as the one shown in below Figure and networks for communications, water supply, or other utilities are constructed with repeated placement of a few graphical shapes.

The shapes used in a design represent the different network or circuit components. Standard shapes for electrical, electronic, and logic Circuits are often supplied by the design package. For other applications, a designer can create personalized symbols that are to be used to construct the network or circuit.

The system is then designed by successively placing components into the layout, with the graphics package automatically providing the connections between components.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 2/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

This allows the designer t~ quickly try out alternate circuit schematics for minimizing the number of components or the space required for the system.

Fig: A circuit design application using

Animations are often used in CAD applications. Real-time animations using wire frame displays on a video monitor are useful for testing performance of a vehicle or system, when we do not display objects with rendered surfaces, the calculations for each segment of the animation can be performed quickly to produce a smooth real-time motion on the screen. Also, wire frame displays allow the designer to **see** into the interior of the vehicle and to watch the behavior of inner components during motion.

Animations in virtual reality environments are used to determine how vehicle operators are affected by certain motions.

This allows the designer to explore various positions of the bucket or backhoe that might obstruct the operator's view, which can then be taken into account in the overall hector design.

### **PRESENTATION GRAPHICS**

Another major application area is presentation graphics, used to produce illustrations for reports or to generate 35-mm slides or transparencies for use with

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 3/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

projectors. Presentation graphics is commonly used to summarize financial, statistical, Mathematical, scientific, and economic data for research reports, managerial reports, consumer information bulletins, and other types of reports.

Workstation devices and service bureaus exist for converting screen displays into 35-mm slides or overhead transparencies for use in presentations. Typical examples of Presentation graphics are bar charts, line graphs, surface graphs, pie charts, and other displays showing relationships between multiple parameters.

(Fig: Two dimensional bar chart and pie chart)

# **COMPUTER ART**

Computer graphics methods are widely used in both fine art and commercial art applications. Artists use a variety of computer methods, including special-purpose hardware, artist's paintbrush (such as Lumens), other paint packages (such as Pixel paint and Super paint), specially developed software, symbolic mathematics packages (such as Mathematics), CAD packages, desktop publishing software, and animation packages that provide facilities for designing object shapes and specifying object motions.

Fine artists use a variety of other computer technologies to produce images. For many applications of commercial art (and in motion pictures and other applications), photo realistic techniques are used to render images of a product.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 4/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

A common graphics method employed in many commercials is morphing, where one object is transformed (metamorphosed) into another. This method has been used in TV commercials to turn an oil can into an automobile engine, an automobile into a tiger, a puddle of water into a tiger, and one person's face into another face

(Fig: Cartoon drawing produced with a paintbrush program)

In above figure illustrates the basic idea behind a paintbrush program that allows artists to "paint" pictures on the screen of a video monitor.

Actually, the picture is usually painted electronically on a graphics tablet (digitizer) using a stylus, which can simulate different brush strokes, brush widths, and colors. A paintbrush program was used to create the characters.

# ENTERTAINMENT

Computer graphics methods are now commonly used in making motion pictures, music videos, and television shows. Sometimes the graphics scenes are displayed by themselves.

• A graphics scene generated for the movie Star Trek-the Wrath of Khan is shown in below figure.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 5/32

LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

(Fig: Graphics developed for the paramount picture movie)

- The planet and spaceship are drawn in wire fame form and will be shaded with rendering methods to produce solid surfaces. Many TV series regularly employ computer graphics methods.
- Music videos use graphics in several ways.

Graphics objects can be combined with the live action, or graphics and image processing techniques can be used to produce a transformation of one person or object into another (morphing).

An example of morphing is shown in the sequence of scenes in below Figure, produced for the David Byme video She's Mad.

(Examples of morphing)

# **EDUCATION AND TRAINING**

Computer-generated models of physical, financial, and economic systems are often used as educational aids. Models of physical systems, physiological systems, population trends, or equipment, such as the color coded diagram in below figure, can help trainees to understand the operation of the system.

For some training applications, special systems are designed. Examples of Such specialized systems are the simulators for practice sessions or training of ship captains, aircraft pilots, heavy-equipment operators, and air traffic control personnel.

Some simulators have no video screens; for example, a flight simulator with only a control panel for instrument flying. But most simulators provide graphics screens for visual operation.

Fig: color coded diagram

# **IMAGE PROCESSING :-**

Although methods used in computer graphics and Image processing overlap, the two areas with fundamentally different operations. In computer graphics, a computer is used to create a picture. Image processing, on the other hand.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 7/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

Applies techniques to modify or interpret existing picture, such as photographs and TV scans.

Two principal applications of image processing are

### (1) Improving picture quality

### (2) Machine perception of visual information,

It is used in robotics. To apply image processing methods, we first digitize a photograph or other Picture into an image file. Then digital methods can be applied to rearrange picture parts, to enhance color separations, or to improve the quality of shading.

**Example** of the application of image processing methods to enhance the quality of a picture is shown

These techniques are used extensively in commercial art applications that involve the retouching and rearranging of sections of photographs and other artwork.

- Similar methods are used to analyze satellite photos of the earth and photos of galaxies.
- Medical applications also make extensive use of image processing techniques for picture enhancements, in tomography and in simulations of operations.

Tomography is a technique of X-ray photography that allows cross-sectional views of physiological systems to be displayed. Both computed X-rav tomography (CT) and position emission tomography (PET) use projection methods to reconstruct cross sections from digital data.

### **GRAPHICAL USER INTERFACES (GUI):-**

It is common now for software packages to provide a graphical interface. A major component of a graphical interface is a window manager that allows a user to display multiple-window areas.

Each window can contain a different process that can contain graphical or no graphical displays. To make a particular window active, we simply click in that window using an interactive pointing device. Interfaces also display menus and icons for fast selection of processing options or parameter values.

An icon is a graphical symbol that is designed to look Like the processing option it represents. The advantages of icons are that they take up less screen space than corresponding textual descriptions and they can be understood more quickly if well designed. Menus contain lists of textual descriptions and icons.

- multiple window areas
- menus and icons

In above figure illustrates a typical graphical interface, containing a window manager, menu displays, and icons.

**Example** the menus allow selection of processing options, color values, and graphics parameters. The icons represent options for painting, drawing, zooming, typing text strings, and other operations connected with picture construction.

### **VIDEO DISPLAY DEVICES :-**

The primary output device in a graphics system is a video monitor (Fig). The operation of most video monitors is based on the standard cathode-ray tube (CRT) design, but several other technologies exist and solid-state monitors may eventually predominate.

Fig: (A computer graphics workstation)

### **REFRESH CATHODE-RAY TUBES**

The basic operation of a CRT. A beam of electrons (cathode rays) emitted by an electron gun, passes through focusing and deflection systems that direct the beam toward specified positions on the phosphor coated screen.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 11/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

The phosphor then emits a small spot of light at each position contacted by the electron beam. Because the light emitted by the phosphor fades very rapidly, some method is needed for maintaining the screen picture.

One way to keep the phosphor glowing is to redraw the picture repeatedly by quickly directing the electron beam back over the same points. This type of display is called a refresh CRT.

The primary components of an electron gun in a CRT are the heated metal cathode and a control grid which is shown in below Figure. Heat is supplied to the cathode by directing a current through a coil of wire, called the filament, inside the cylindrical cathode structure.

This causes electrons to be 'boiled off" the hot cathode surface. In the vacuum inside the CRT envelope, the free, negatively charged electrons are then accelerated toward the phosphor coating by a high positive voltage.

(Fig: basic design of magnetic deflection CRT)

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 12/32

# ILASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

The accelerating voltage can be generated with a positively charged metal coating on the inside of the CRT envelope near the phosphor screen, or an accelerating anode can be used,

Sometimes the electron gun is built to contain the accelerating anode and focusing system within the same unit.

(Fig: Operation of the electron gun with an accelerating anode)

Intensity of the electron beam is controlled by setting voltage levels on the control grid, which is a metal cylinder that fits over the cathode.

A high negative voltage applied to the control grid will shut off the beam by repelling electrons and stopping them from passing through the small hole at the end of the control grid structure.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 13/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

A smaller negative voltage on the control grid simply decreases the number of electrons passing through. Since the amount of light emitted by the phosphor coating depends on the number of electrons striking the screen, we control the brightness of a display by varying the voltage on the control grid.

The focusing system in a CRT is needed to force the electron beam to converge into a small spot as it strikes the phosphor. Otherwise, the electrons would repel each other, and the beam would spread out as it approaches the screen.

Focusing is accomplished with either electric or magnetic fields. Electrostatic focusing is commonly used in television and computer graphics monitors. With electrostatic focusing, the electron beam passes through a positively charged metal cylinder that forms an electrostatic lens.

The action of the electrostatic lens focuses the electron beam at the center of the screen, in exactly the same way that an optical lens focuses a beam of light at a particular focal distance.

Similar lens focusing effects can be accomplished with a magnetic field set up by a coil mounted around the outside of the CRT envelope. Magnetic lens focusing produces the smallest spot size on the screen and is used in special purpose Devices.

Additional focusing hardware is used in high-precision systems to keep the beam in focus at all screen positions. The distance that the electron beam must travel to different points on the screen varies because the radius of curvature for most CRTs is greater than the distance from the focusing system to the screen center.

Cathode-ray tubes are now common. Constructed with magnetic deflection coils mounted on the outside of the CRT envelope.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 14/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

Two pairs of coils are used, with the coils in each pair mounted on opposite sides of the neck of the CRT envelope.

- One pair is mounted on the top and bottom of the neck and
- The other pair is mounted on opposite sides of the neck

The magnetic, field produced by each pair of coils results in a transverse deflection force that is perpendicular both to the direction of the magnetic field and to the direction of travel of the electron beam. Horizontal deflection is accomplished with one pair of coils, and vertical deflection by the other pair.

The proper deflection amounts are attained by adjusting the current through the coils. When electrostatic deflection is used, two pairs of parallel plates are mounted inside the CRT envelope. One pair of plates is mounted horizontally to control the vertical deflection, and the other pair is mounted vertical to control horizontal deflection.

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

Spots of light are produced on the screen by the transfer of the CRT.

Remainder causes electrons in the phosphor atoms to move up to higher quantumenergy levels. After a short time, the "excited phosphor electrons begin dropping back to their stable ground state, giving up their extra energy as small quantum of Light energy.

The electron light emissions: a glowing spot that quickly fades after all the excited phosphor electrons have returned to their ground energy level. The frequency (or color) of the light emitted by the phosphor is proportional to the energy difference between the excited quantum state and the ground state.

# **RASTER-SCAN DISPLAYS :-**

The most common type of graphics monitor employing a CRT is the raster-scan display, based on television technology.

In a raster-scan system, the electron beam is swept across the screen, one row at a time from top to bottom. As the electron beam moves across each row, the beam intensity is turned on and off to create a pattern of illuminated spots.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 16/32

# COURSE CODE: 16MMU503B

### COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

• Picture definition is stored in a memory area called the refresh buffer or frame buffer.

This memory area holds the set of intensity values for all the screen points.

- Stored intensity values are then retrieved from the refresh buffer and "painted" on the screen one row (scan line) at a time (in above Figure).
- Each screen point is referred to as a pixel or pel (shortened forms of picture element).
- Intensity range for pixel positions depends on the capability of the raster system. In a simple black-and-white system, each screen point is either on or off, so only one bit per pixel is needed to control the intensity of screen positions.
- For a bi-level system, a bit value of 1 indicates that the electron beam is to be turn on at that position,
- And a value of 0 indicates that the beam intensity is to be off.
- Additional bits are needed when color and intensity variations can be displayed. Up to 24 bits per pixel are included in high-quality systems, which can require several megabytes of storage for the frame buffer, depending on the resolution of the system.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 17/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

A system with 24 bits per pixel and a screen resolution of 1024 by 1024 requires 3 megabytes of storage for the frame buffer. On a black-and-white system with one bit per pixel, the frame buffer is commonly called a bitmap.

For systems with multiple bits per pixel, the frame buffer is often referred to as a pixmap.

Refreshing on raster-scan displays is carried out at the rate of 60 to 80 frames per second, although some systems are designed for higher refresh rates. Sometimes, refresh rates are described in units of cycles per second, or Hertz (Hz), where a cycle corresponds to one frame. Using these units, we would describe

# **RANDOM-SCAN DISPLAYS**

A random-scan display unit, a CRT has the electron beam directed only to the parts of the screen where a picture is to be drawn.

Random scan monitors draw a picture one line at a time and for this reason are also referred to as vector displays *(or stroke-writing or calligraphic displays).* 

The Component lines of a picture can be drawn and refreshed by a random-scan system in any specified order which is shows in below figure.

(Fig: Interlacing scan lines on the raster scan system)

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 18/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

Refresh rate on a random-scan system depends on the number of lines to be displayed. Picture definition is now stored as a set of line drawing commands in an area of memory r e f e d to as the refresh display file.

Sometimes the refresh display file is called the display list, display program, or simply the refresh buffer.

To display a specified picture, the system cycles through the set of commands

After all line drawing commands have been processed, the system cycles back to the first line command in the list. Random-scan displays are designed to draw all the component lines of a picture 30 to 60 times each second.

High quality vector systems are capable of handling approximately 100,000 "short" lines at this refresh rate. When a small set of lines is to be displayed, each refresh cycle is delayed to avoid refresh rates greater than 60 frames per second. Otherwise, faster refreshing of the set of lines could bum out the phosphor.

Random-scan systems are designed for line drawing applications and cannot display realistic shaded scenes. Since picture definition is stored as a set of line drawing instructions and not as a set of intensity values for all screen points, vector displays generally have higher resolution than raster systems. Also, vector displays produce smooth line drawings because the CRT beam directly follows the line path.

### **COLOR CRT MONITORS:-**

### **Color Monitors:**

A color CRT monitor displays color picture by using a combination of phosphors that emit different colored light. By combining the emitted light a range of colors can be generated. Two basic methods for producing color displays are:

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 19/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

- Beam Penetration Method
- Shadow-Mask Method

### **Beam Penetration Method**

Random scan monitors use the beam penetration method for displaying color picture. In this, the inside of CRT screen is coated two layers of phosphor namely red and green. A beam of slow electrons excites only the outer red layer, while a beam of fast electrons penetrates red layer and excites the inner green layer. At intermediate beam speeds, combinations of red and green light are emitted to show two additional colors-orange and yellow.

### <u>Advantages</u>

• Less expensive

### **Disadvantages**

- Qualities of images are not good as comparatable with other methods
- Four colors are allowed only

### **Shadow Mask Method**

Raster scan system are use shadow mask methods to produce a much more range of colors than beam penetration method. In this, CRT has three phosphor color dots. One phosphor dot emits a red light, second emits a green light and third emits a blue light. This type of CRT has three electrons guns and a shadow mask grid as shown in figure below:

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

In this figure, three electrons beams are deflected and focused as a group onto the shadow mask which contains a series of holes. When three beams pass through a hole in shadow mask they activate dot triangle as shown in figure below:

The colors we can see depend on the amount of excitation of red, green and blue phosphor. A white area is a reasult of all three dots with equal intensity while yellow is produced with green and red dots and so on.

### <u>Advantages</u>

• Produce realistic images also produced different colors and shadows scenes.

### <u>Disadvantages</u>

- low resolution
- expensive
- electron beam directed to whole screen

Color CRTs in graphics systems are designed as RGB monitors. These monitors use shadow mask method and take the intensity level for each gun. A RGB color system with 34 bits of storage per pixel is known as full color system or true color system.

### DIRECT VIEW STORAGE TUBES:

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 21/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

- An Alternative method for maintaining a screen image is to store the picture information inside the CRT instead of refreshing the screen.
- DIRECT VIEW STORAGE TUBES stores the picture information as the phosphor-coated screen
- Two electron guns are used in DVST

### 1. Primary Gun-store the picture pattern

2. Flood Gun-Maintains the picture display.

### **ADVANTAGES:**

Very complex pictures can be displayed at very high resolutions without ficker.

### **DISADVANTAGES:**

- In DVST system ordinarily do not display color and that selected parts of a picture cannot be erased To eliminate a picture section the entire screen must be erased and the modified picture redrawn.
- The erasing and redrawing process can take several seconds for a complex picture.

# FLAT-PANEL DISPLAYS:

Although most graphics monitors are still constructed with CRT .Other technologies are emerging that soon replace CRT monitors.

- Flat panel display is referred to class of video devices that have reduce volume weight and power requirements compared to a CRT.
- Flat panel display is that they are thinner than CRTs.
- Since we can write on some flat panel display they will soon be available as pocket notepads.

### **CURRENT USES:**

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 22/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

Small TV monitors, Calculators, Pocket video games, laptop computers and viewing of movies on airlines, advertisement boards in elevators and portable monitors etc.

Flat-panel displays can be divided into two types:

### 1. Emissive display

### 2. Non emissive display

- Emissive display- are device that convert electrical energy into light. Examples:-plasma panels,thin flim,electroluminescent display and light emitting diodes
- Non Emissive display-use optical effects to convert sunlight or light from other sources into graphics pattern

Examples:liquid crystal device

- Plasma panel- also called gas-discharge displays are constructed by filling the region between two glass plates with a mixture of gasses
- Plasma display panels are most often seen as large flat televisions, while vacuum fluorescent displays are used in applications where the information content is fairly low, such as the displays on appliances or in automobiles. Field-emission displays are the most recent of these flat-panel technologies

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 23/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

- Thin-Film electroluminescent displays:-are similar constructions to a plasma panel. The difference is that region between glass plates is filled with a phosphor .
- A third type of emissive device is the LIGHT -EMITTING DIODE (LED)-A matrix of diodes is arranged to form the pixel positions.

### LIQUID CRYSTAL DISPLAY:-

- Liquid crystal displays (LCDS) are commonly used in small systems, such as calculators and portable, laptop computers.
- These non emissive devices produce a picture by passing polarized light from the surroundings or from an internal light **s** o **w** through a liquid-crystal material that can be aligned to either block or transmit the light.
- A flat-panel display can then be constructed with a nematic liquid crystal

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 24/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

- Two glass plates, each containing a light polarizer at right angles to the other plate, sandwich the liquid-crystal material. Rows of horizontal transparent conductors are built into one glass plate, and columns of vertical conductors are put into the other plate.
- The intersection of two conductors defines a pixel position. Normally, the molecules are aligned as shown in the above figure "on state".

### **3D-VIEWING DEVICES:-**

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE 25/32
# COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

Graphics monitors for the display of three-dimensional scenes have been devised using a technique that reflects a CRT image from a vibrating, flexible mirror.

The operation of such a system is demonstrated in below figure. As the varifocal mirror vibrates, it changes focal length. These vibrations are synchronized with the display of an object on a CRT so that each point on the object is reflected from the mirror into a spatial position corresponding to the distance of that point from a specified viewing position. This allows us to walk around an object or scene and view it from different side.

LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

# **RASTER SCAN SYSTEMS:-**

Raster graphics systems typically employ several processing units. In addition to the central processing unit, or CPU, a special-purpose processor, called the video controller or display controller, is used to control the operation of the display device.

1. Video Controller

2. Raster scan display processor

### Video Controller

A fixed area of the system memory is reserved for the frame buffer, and the video controller is given direct access to the frame-buffer memory.

Frame-buffer locations, and the corresponding screen positions, are referenced in Cartesian coordinates.

The screen surface is then represented as the first quadrant of a two-dimensional system, with positive x values increasing to the right and positive y values increasing from bottom to top. Scan lines *are* then labeled from y, at the top of the screen to 0 at the bottom. Along each scan line, screen pixel positions are labeled from 0 to  $x_{max}$

LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

### **RASTER SCAN DISPLAY PROCESSOR:**

The purpose of the display processor is to free the CPU from the graphics chores. In addition to the system memory, a separate display processor memory area can also be provided.

Architecture of raster scan display processor

### RANDOM SCAN SYSTEM:

The organization of a simple random-scan (vector) system is shown in below figure. An application program is input and stored in the system memory along with a graphics package. Graphics commands in the application program are translated.

- The graphics package into a display file stored in the system memory.
- This display file is then accessed by the display processor to refresh the screen.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications ,KAHE 29/32

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

• The display processor cycles through each command in the display file program once during every refresh cycle. Sometimes the display processor in a random-scan system is referred to as a display processing unit or a graphics controller.

# **RANDOM SCAN SYSTEM:-**

The organization of a simple random-scan (vector) system is shown in below figure. An application program is input and stored in the system memory along with a graphics package.

Graphics commands in the application program are translated by the graphics package into a display file stored in the system memory. This display file is then accessed by the display processor to refresh the screen.

The display processor cycles through each command in the display file program once during every refresh cycle. Sometimes the display processor in a random-scan system is referred to as a display processing unit or a graphics controller.

Graphics patterns are drawn on a random-scan system by directing the electron beam along the component lines of the picture.

# LASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: I BATCH: 2016-2019

Lines are defined by the values for their coordinate endpoints, and these input coordinate values are converted to x and y deflection voltages. A scene is then drawn one line at a time by positioning the beam to fill in the line between specified endpoints.

### **CHARACTER GENERATORS**

A character generator, often abbreviated as CG, is a device or software that produces static or animated text (such as news crawls and credits rolls) for keyinginto a video stream. Modern character generators are computer-based, and can generate graphics as well as text. The integrated circuit, usually in the form of a PROM, that decodes a keystroke in a keyboard, and outputs a corresponding character, is also referred to as a "character generator.

### POSSIBLE QUESTIONS UNIT I

### PART-A (20 Marks)

### (Q.No 1 to 20 Online Examination)

### PART-B (2 Marks)

- 1. Define Computer Graphics?
- 2. Define CRT?
- 3. Define Random scan display
- 4. Define Raster scan Display.
- 5. What are Character Generators

### Part -C (6 Marks)

- 1. Discuss about Color CRT Monitors
- 2. Write the working principles of Refresh CRT and a detail description of each component in CRT
- 3. Explain the two basic techniques used in Color CRT monitor with a neat diagram
- 4. Give a detailed account on flat panel displays
- 5. Differentiate between Random and Raster Scan Display
- 6. Discuss about color CRT monitors
- 7. Give a Detailed account on Raster Scan Systems.
- 8. Explain about Color CRT Monitors
- 9. Explain in detail about Refresh Cathode Ray Tube
- 10. What are the various applications of computer graphics

# UNIT II

# **SYLLABUS**

Input Devices: Keyboards - Mouse – Track Ball and Space ball – Joysticks - Data Glove – Digitizers -Image Scanners - Touch Panels - Light Pens - Voice Systems. Hard Copy Devices: Printers and Plotters, Interactive input/output devices

Point, lines and Curves : Scan conversion, Line Drawing Algorithms: DDA Algorithm - Bresenhams Line Algorithm. Circle Generating Algorithms: Mid Point Circle Algorithm, Ellipse Generating Algorithm, Conic-section generation, polygon filling anti aliasing.

# **INPUT DEVICES:-**

Various devices *are* available for data input on graphics workstations. Most systems have a keyboard and one or more additional devices specially designed for iterative input. These include a mouse, trackball, space ball, joystick, digitizers, dials, and button boxes. Some other inputs devices are used In particular applications are data gloves, touch panels, image scanners, and voice systems.

# **KEYBOARD:-**

An alphanumeric keyboard on a graphics system is used primarily as a device for entering text strings.

- The keyboard is an efficient device for inputting such non graphic data as picture labels associated with a graphics display.
- Keyboards can also be provided with features to facilitate entry of screen coordinates, menu selections, or graphics functions.
- Cursor-control keys and function keys are common features on general purpose keyboards.
- Function keys allow users to enter frequently used operations in a single keystroke, and cursorcontrol keys can be used to select displayed objects or coordinate positions by positioning the screen cursor.

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: II BATCH: 2016-2019

Other types of cursor-positioning devices, such as a trackball or joystick, are included on some keyboards. Additionally, a numeric keypad is, often included on the keyboard for fast entry of numeric data. Typical examples of general-purpose keyboards.

Alphanumeric Keys - letters and numbers.

Punctuation Keys - comma, period, semicolon, and so on. Special Keys - function keys, control keys, arrow keys, Caps Lock key, and so on.

### **MOUSE:**

A mouse is small hand-held box used to position the screen cursor. Wheels or rollers on the bottom of the mouse can be used to record the amount and direction of movement.

Another method for detecting mouse motion is with an optical sensor. For these systems, the mouse is moved over a special mouse pad that has a grid of horizontal and vertical lines. The optical sensor detects movement across the lines in the grid.

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: II BATCH: 2016-2019

A mouse can be picked up and put down at another position without change in cursor movement; it is used for making relative change in the position of the screen cursor. One, two, or three button usually included on the top of the mouse for signaling the execution of some operation, such as recording cursor position or invoking a function.

Additional devices can be included in the basic mouse design to increase the number of allowable input parameters. The Z mouse includes three buttons, a thumbwheel on the side, a trackball on the top, and a standard mouse ball underneath.

This design provides six degrees of freedom to select Input Devices spatial positions, rotations, and other parameters. With the Z mouse, we can pick up an object, rotate it, and move it in any direction, or we can navigate our viewing position and orientation through a three-dimensional scene. Applications of the Z mouse include virtual reality, CAD, and animation.

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

COURSE NAME: COMPUTER GRPHICS UNIT: II BATCH: 2016-2019

### TRACKBALL AND SPACE BALL:-

Trackball is a ball that can be rotated with the fingers or palm of the hand, to produce screencursor movement.

Potentiometers, attached to the ball, measure the amount and direction of rotation. Trackballs are often mounted on keyboards or other devices such as the Z mouse.

• While a trackball is a two-dimensional positioning device,

### **SPACE BALL:-**

Space ball provides six degrees of freedom. Unlike the trackball, a space ball does not actually move. Strain gauges measure the amount of pressure applied to the space ball to provide input for spatial positioning and orientation as the ball is pushed or pulled in various directions.

• Space balls are used for three-dimensional positioning and selection operations in virtual-reality

systems, modeling, animation, CAD, and other applications.

### **JOYSTICKS:-**

A joystick consists of a small, vertical lever (called the stick) mounted on a base that is used to steer the screen cursor around.

Most joysticks select screen positions with actual stick movement others respond to pressure on the stick. Some joysticks are mounted on a keyboard others function as stand-alone units.

The distance that the stick is moved in any direction from its center position corresponds to screen-cursor movement in that direction. Potentiometers mounted at the base of the joystick measure the amount of movement, and springs return the stick to the center position when it is released. One or more buttons can be programmed to act as input switches to signal certain actions once a screen position has been selected.

In another type of movable joystick, the stick is used to activate switches that cause the screen cursor to move at a constant rate in the direction selected. Eight switches, arranged in a circle, are sometimes provided, so that the stick can select any one of eight directions for cursor movement. Pressure sensitive joysticks, also called isometric joysticks, have a non movable stick.

### **JOYSTICKs**

# **DATA GLOVE:-**

Data glove that can be used to grasp a "virtual" object. The glove is constructed with a series of sensors that detect hand and finger motions.

- Electromagnetic coupling between transmitting antennas and receiving antennas is used to provide information about the position and orientation of the hand.
- The transmitting and receiving antennas can each be structured as a set of three mutually perpendicular coils, forming a three-dimensional Cartesian coordinate system.
- Input from the glove can be used to position or manipulate objects in a virtual scene.
- A two-dimensional projection of the scene can be viewed on a video monitor, or a threedimensional projection can be viewed with a headset.

(Fig: A virtual reality screen displayed on a 2-D video monitor with input from data glove and a Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE 6/33

space ball)

# **DIGITIZERS:-**

A common device for drawing, painting, or interactively selecting coordinate positions on an object is a digitizer. These devices can be used to input coordinate values in either a two-dimensional or a three-dimensional space.

Typically, a digitizer is used to scan over a drawing or object and to input a set of discrete coordinate positions, which can be joined with straight- line segments to approximate the curve or surface shapes.

One type of digitizer *is* the graphics tablet (also referred to as a data tablet), which is used to input two-dimensional coordinates by activating a hand cursor or stylus at selected positions on a flat surface. A hand cursor contains cross hairs for sighting positions, while a stylus is a pencil-shaped device that is pointed at positions on the tablet.

- Many graphics tablets are constructed with a rectangular grid of wires embedded in the tablet surface.
- Three-dimensional digitizers use sonic or electromagnetic transmissions to word positions. One electromagnetic transmission method is similar to that used in the data glove.
- A coupling between the transmitter and receiver is used to compute the location of a stylus as it moves over the surface of an object.

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# COURSE NAME: COMPUTER GRPHICS UNIT: II BATCH: 2016-2019

DIGITIZERS

### **IMAGE SCANNERS:-**

Drawings, graphs, color and black-and-white photos, or text can be stored for computer processing with an image scanner by passing an optical scanning mechanism over the information to be stored.

The gradations of gray scale or color are then recorded and stored in an array. Once we have the internal representation of a picture, we can apply transformations to rotate, scale, or crop the picture to a particular screen area. We can also apply various image-processing methods to modify the array representation of the picture.

For scanned text input, various editing operations can be performed on the stored documents. Some scanners are able to scan either graphical representations or text, and they come in a variety of sizes and capabilities.

IMAGE SCANNERS

### **TOUCH PANELS:-**

Touch panels allow displayed objects or screen positions to be selected with the touch of a finger. A typical application of touch panels is for the selection of processing options that are represented with graphical icons. Some systems, such as the plasma panels are designed with Touch screens

Other systems can be adapted for touch input by fitting a transparent device with a touch sensing mechanism over the video monitor screen. Touch input can be recorded using optical, electrical, or acoustical methods. Optical touch panels employ a line of infrared light-emitting diodes (LEDs)

Along one vertical edge and along one horizontal edge of the frame. The opposite vertical and horizontal edges contain light detectors. These detectors are used to record which beams are interrupted when the panel is touched.

The two crossing beams that are interrupted identify the horizontal and vertical coordinates of the screen position selected. Positions tin be selected with an accuracy of about <sup>1</sup>/<sub>4</sub> inch With closely spaced LEDs,

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: II BATCH: 2016-2019

The LEDs operate at infrared frequencies, so that the light is not visible to a user. The arrangement of LEDs in an optical touch panel that is designed to match the color and contours of the system to which it is to be fitted.

An electrical touch panel is constructed with two transparent plates separated by a small distance

- 1. One of the plates is coated with a conducting material,
- 2. and the other plate is coated with a resistive material

In acoustical touch panels, high-frequency sound waves are generated in the horizontal and vertical directions across a glass plate. Touching the screen causes part of each wave to be reflected from the finger to the emitters.

The screen position at the point of contact is calculated from a measurement of the time interval between the transmission of each wave and its reflection to the emitter.

TOUCH PANEL

# **LIGHT PENS:-**

In the below figure shows the design of one type of light pen. Such pencil-shaped devices are **Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE** 10/33

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B UNIT: II

# COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

used to select screen positions by detecting the light coming from points on the CRT screen They are sensitive to *the* short burst of light emitted from the Phosphor coating at the instant the electron beam strikes a particular point. Other Light sources, such as the background light in the room, are usually not detected by a light pen.

An activated light pen, pointed at a spot on the screen as the electron beam lights up that spot, generates an electrical pulse that causes the coordinate position of the electron beam to be recorded. As with cursor-positioning devices, recorded Light-pen coordinates can be used to position an object or to select a processing option.

# (Fig: Light pen)

• Although Light pens are still with us, they are not as popular.

### **DISADVANTAGES:-**

- Command to other input devices that have been developed. For one, when a light pen is pointed at the screen, part of the screen image is obscured by the hand and pen.
- Light pens require special implementations for some applications because they cannot detect positions within black areas.
- To be able to select positions in any screen area with a light pen, we must have some

nonzero intensity assigned to each screen pixel. In addition, light pens. Sometimes give false readings due to background lighting in a room.

# **VOICE SYSTEMS:-**

Speech recognizers are used in some graphics workstations as input devices to accept voice commands the voice-system input can be used to initiate graphics operations or to enter data.

These systems operate by matching an input against predefined dictionary of words and phrases. A dictionary is set up for a particular operator by having, the operator speak the command words to be used into the system. Each word is spoken Several times, and the system analyzes the word and establishes a frequency pattern for that word in the dictionary along with the corresponding function to be performed.

Later, when a voice command is given, the system searches the dictionary for a frequencypattern match. Voice input is typically spoken into a microphone mounted on a headset, as in below

Fig. The microphone is designed to minimize input of other background sounds. If a different operator is to use the System, the dictionary must be reestablished with that operator's voice patterns. Voice systems have some advantage over other input devices, since the attention of the operator does not have to be switched from one device to another to enter a command.

### HARD-COPY DEVICES:-

### **PRINTERS:**

Printers are the most commonly used output device. They are used to print output on the paper. The output may be in the form of characters, symbols and graphics information printed on paper is called hardcopy

The various types of printers in used today are

- **1. Dot-Matrix Printers**
- 2. Inkjet Printers
- 3. Drum Printers
- 4. Laser Printers.

Printers produce output by either

- 1. Impact Printer
- 2. Non impact Printer

### 1. Impact Printer

The types of printers that produce output on paper by striking the print hammer or wheel against an inked ribbon are called impact printers. Impact printers work like typewriter. They can print characters and graphics on the paper.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE 13/33

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

# COURSE NAME: COMPUTER GRPHICS UNIT: II BATCH: 2016-2019

Impact printers are slower in printing and produce low quality output. The printing speed of these printers is measured in characters or lines per minute. They also produce more noise during printing. Today they are not commonly used.

### The examples of impact printers are:

- **1- Dot matrix printer**
- 2- Daisy Wheel printer
- 3- Line printer

### **DOT MATRIX PRINTERS:**

A dot matrix printer is an impact character printer. It makes a hardcopy by printing one character at a time. Its printing speed is from 200 to 1000 or more characters per minute.

Dot matrix printer contains a print-head with a matrix of small pins arranged in rows and columns. Dot matrix printer produces output on paper by striking pins against an ink ribbon. Usually, a dot matrix printer uses 100 to 300 dots per inch (DPI) to print output on the paper. Print-heads are avialable with 9, 18 or 24 pins. The dot matrix printer with 24-pins provides best quality printout.

Dot matrix printers are used with personal computer. They are less expensive. The printout quality of these printers is not bad. They also produce more noise during printing.

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

UNIT: II

COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

### DOT MATRIX PRINTER

### **DAISY WHEEL PRINTER:-**

Daisy wheel printer is also an impact character printer. It is similar to typewriter. It has a print wheel with a series of petals. This wheel is known as daisy wheel. Each petal of daisy wheel contains a character at its end.

A motor rotates the wheel. When the desired character reaches at the print position on the paper, a hammer strikes a petal against the ribbon. In this way, a character is printed on the paper. This printer is slower than dot-matrix printer. However, its print quality is better than dot matrix printer

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

COURSE NAME: COMPUTER GRPHICS UNIT: II BATCH: 2016-2019

DAISY WHEEL PRINTER

### LINE PRINTER:-

Line printer is an impact printer. it is very fast printer. It prints a complete line of characters at a time. The printing speed of line printer is measured in lines per minute (lpm). It is up to 3000 lines per minute.

Line printers are normally used with mainframe and mini computers.

Two types of line printers are:-

- 1- Chain Printer
- 2- Band Printer

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE 16/33

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

UNIT: II

# COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

# 2. NON IMPACT PRINTERS:-

The printers that produce output on paper without striking the paper are known as non-impact printers. They Use Electrostatic, inkjet, and thermal technologies for printing.

Non-Impact printers are faster and produce high quality output than impact printers. They can print up to 24 pages per minute. They produce no noise during printing. These printers are costly than impact printers

### The Examples of Non-Impact printers are:

- 1- Laser Printer
- 2- Inkjet Printer
- **3-** Thermal Printer

### Laser Printer

Laser stands for Light Amplification by Simulated Emission of Radiation. A laser printer is the fastest and high quality non-impact printer. It works like a photocopier.

The laser printer transfers the image of output on paper using LASER technology and toner. Toner is an ink powder. It is used in laser printers and photocopiers .

# KARPAGAM

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICSCOURSE NAME: COMPUTER GRPHICSCOURSE CODE: 16MMU503BUNIT: IIBATCH: 2016-2019

The laser printer has a special drum inside it. first the image of output is created on the drum, and then it is transferred from drum to paper. The image of output is created on the drum by throwing magnetic ink powder in the form of microscopic dots.

These dots can be from 300 dpi to 1200 dpi (dpi means dots per inch and these dots refers to microscopic dots).

The Laser printer can print both text and graphics in very high quality resolution. Laser printer prints one page at a time. The laser printers are, therefore also called page printers. The printing speed of laser printer is about 4 to 32 pages per minute for microcomputer and up to 200 pages per minute for mainframe computers.

### **Ink Jet Printer**

Ink-jet printer is type of non-impact printer. It creates output on paper by spraying tiny drops of liquid ink. Inkjet printer has print-head that can spray very fine drops of ink. It consists of print cartridge filled with liquid ink and has small nozzles in form of matrix.

Like dot matrix printer, the combination of nozzles is activated to form the shaper of character or image on the paper by spraying the liquid ink. These printers have resolution ranging from 300 to 720 dpi.

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

COURSE NAME: COMPUTER GRPHICS UNIT: II BATCH: 2016-2019

#### INK JET PRINTER

The ink-jet printers have low price than laser printers. They are also slower and have low print quality than laser printer. However, they are faster and have high print quality than dot matrix printers. The printing speed of ink-jet printer is from 1 to minute. 6 pages per

### **Thermal Printer**

Thermal printer is another type of non-impact printer. It can only print output on a special heat sensitive waxy paper. The image if the output is created on the waxy paper by burning dots on it. For colored output, colored waxy sheets are used.

### **KARPAGAM ACADEMY OF HIGHER EDUCATION**

# **CLASS: III B.SC MATHEMATICS** COURSE CODE: 16MMU503B

#### **COURSE NAME: COMPUTER GRPHICS UNIT: II** BATCH: 2016-2019

THERMAL PRINTER

Thermal Printer produces a high quality printout. It is quite expansive as compared to other non-impact printers.

Line Drawing Algorithms

Equation of straight line is y = mx + b, where m is the slope of straight line and b is the y intercept.

 $M = \frac{y^2 - y^1}{x^2 - x^1} = \frac{\Delta y}{\Delta x}$ 

- If |m| < 1 then  $\Delta x$  is proportional to  $\Delta y$ .
- If |m| > 1 then  $\Delta y$  is proportional to  $\Delta x$ .
- Any change in  $\Delta x$  is called as horizontal deflection, any change in  $\Delta y$  is called as vertical deflection.  $\Delta y$  Or  $\Delta x$ .

### **DDA Line Drawing Algorithm**

DDA is a scan conversion line algorithm based on calculating either  $\Delta y$  or  $\Delta x$ . We sample the line at unit intervals in one coordinate and determine corresponding integer nearest to the line path for the other coordinates. Line drawing is accomplished by calculating intermediate positions along the line path between two specified end points. Digital devices display a straight-line segment by plotting discrete points between two end points. Discrete coordinates along the

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE

# CLASS: III B.SC MATHEMATICSCOURSE NAME: COMPUTER GRPHICSCOURSE CODE: 16MMU503BUNIT: IIBATCH: 2016-2019

line path are calculated from line equations. Screen locations are referenced with integer values; so plotted positions may only approximate actual line positions between two specified endpoints. The rounding of co-ordinate values to integers causes lines to be displayed with a stair step appearance. To load an intensity value into the frame buffer at a position to column x and line y, the procedure used is

Setpixel (x, y, intensity)

To retrieve the current frame buffer intensity by calling the procedure

Getpixel(x, y)

DDA algorithm is a faster method for calculating pixel positions. The accumulation of round off error in successive additions of the floating-point increment causes the calculated pixel positions to drift away from the true line path for long line segment. The rounding operations & floating-point arithmetic in DDA procedure is time-consuming. The Cartesian slope intercept equation for a straight line is

 $y=m.x+b \rightarrow (1)$ 

Here m represents slope of the line and b represents y intercept. Let us consider two end points are  $(x_1, y_1) \& (x_2, y_2)$ .

Calculating slope and intercept values

 $m=y2-y1 / x2-x1 \rightarrow (2)$   $b=y1-m.x1 \rightarrow (3)$   $\Delta y=m.\Delta x \rightarrow (4)$  $\Delta x=\Delta y/m \rightarrow (5)$ 

Slope magnitudes can set deflection of the voltage.

Lines with the slope magnitude |m|<1,  $\Delta x$  have proportional to a small horizontal deflection voltage & vertical deflection proportional to  $\Delta y$ .

 $|m|>1 \Delta y$  set to small vertical deflection & horizontal deflection is set to  $\Delta x$ .

m=1  $\Delta x = \Delta y$  horizontal and vertical deflection are equal.

DDA algorithm draws lines at unit intervals in one co-ordinate and determines corresponding integer values nearest the line path for the other co-ordinate.

If it is a positive slope

(1) The slope is less than or equal to 1 compute each successive y as

 $Y_{k^{\!+}\,l}\,{}_{=}\,Y_k\,{}^{\!+}\,m$ 

Subscript k takes integer value starting from 1 and increase by 1 until the final end point is reached.

(2) the slope is greater than 1 then calculate each succeeding x value as

 $X_{k+1} = X_k + (1/m)$ 

If the process is from right point to left (ie reverse)

$$\mathbf{Y}_{k+1} = \mathbf{Y}_k - \mathbf{m}$$

 $X_{k+1} = X_k - (1/m)$ 

DDA algorithm accepts as a input the two end point pixel positions. Find Horizontal and vertical differences between endpoints positions are assigned to parameters dx and dy. The difference with greater magnitude determines the value of parameter steps. Starting with pixel position (xa, ya), generate next pixel position along the line path. Loop through this process steps times. The value of x and y will get incremented by using algorithm calculations. Then call setpixel for plot pixel. DDA algorithm is faster method. The following algorithm explains the line drawings.

```
#include "device.h"
#define ROUND (a) ((int) (a+0.5))
void lineDDA (int xa, int ya, int xb, int yb)
{
    Int dx=xb-xa, dy=yb-ya, steps, k;
    float xIncrement, yIncrement, x=xa, y=ya;
    if ( abs(dx) > abs(dy) ) then steps := abs(dx);
      else steps := abs(dy);
      xIncrement := dx / (float) steps;
      yIncrement := dy / (float) steps;
      setPixel (ROUND(x), ROUND(y));
      for (k := 0;k<steps; k++) {
</pre>
```

}

}

### KARPAGAM ACADEMY OF HIGHER EDUCATION

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

## COURSE NAME: COMPUTER GRPHICS UNIT: II BATCH: 2016-2019

```
x := x + xIncrement;
y := y + yIncrement;
setPixel (ROUND(x), ROUND(y));
```

Disadvantage: - round of function – drift away from the true line path for long line segment.

### Bresenham's Line Drawing Algorithm:

An accurate and efficient raster line generating algorithm, developed by Bresenham, scan converts lines only incremental integer calculation that can be adapted to display circles and other curves. The vertical axes show scan-line positions, and the horizontal axes identity pixel columns. Sampling at unit x intervals in these intervals, we need to find the next closest pixel position in the line, whose value is proportional to difference between the separations of the two pixel positions from the actual path.

Starting from the left endpoint (10,11) we need to determine at the next sample position whether to plot at position (11, 11) or the one at (11, 12). These questions are answered with Bresenham's line algorithm by testing the sign of an integer parameter, whose value is proportional to the difference between the separations of the two pixel positions from the actual line path.

Consider the scan conversion process for lines with positive slope less than 1.Pixel positions along line path are then determined by sampling at unit x intervals. Starting from left end point(xo,yo) of a given line, we step to each successive column and plot pixel whose scan line value is closest to the line path. Assume we have determined that the pixel ( $x_{k,y_k}$ ) is to be displayed. Next has to decide which pixel to plot in column  $x_{k+1}$ .

### COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

The line equation is  $y=m(x_k+1)+b \rightarrow eq1$ )

 $d1 = y \cdot y_k \implies m(x_k + 1) + b \cdot y_k$  // implemented in eq1

d2 =  $(y_k+1)-y = \rightarrow y_k+1-m(x_k+1)-b//$  implemented in eq1.

The differences between these two separators are

 $M = \Delta y / \Delta x$ 

$$d1 - d2 = 2m(x_k+1)-2y_k+2b-1$$

A decision parameter  $P_k$  for k th step.

 $P_k = \Delta x(d1-d2)$ 

The first parameter can be calculated by the equ  $p_0=2\Delta y-\Delta x$ .

Next point can calculated by  $p_{k+1}=p_k+2\Delta y$  and  $p_{k+1}=p_k+2\Delta y$ .

Bresenham's Line – Drawing Algorithm

- Input the two line endpoints and store the left endpoint in (x<sub>0</sub>, y<sub>0</sub>).
- Load  $(x_0,y_0)$  into the frame buffer; that is plot the first point.
- Calculate constants  $\Delta x$ ,  $\Delta y$ ,  $2\Delta y$ , and  $2\Delta y 2\Delta x$ , and obtain the starting value for the decision parameter as

$$\mathbf{p}_0 = 2\Delta \mathbf{y} - \Delta \mathbf{x}$$

• At each  $x_k$  along the line, starting at k = 0, perform the following test:

#### **<u>Circle Generation Algorithm</u>**

Properties of a circle:

A circle is defined as the set of points that are all at a given distance r from a center position  $(x_c, y_c)$ .

Pythogorean theorm in caretisan coordinates as  $(x-x_c)^2 + (y-y_c)^2 = r^2$ 

By using this calculate position of points on a circle circumference by stepping along the x axis in unit steps from  $x_c$  -r to  $x_c$  +r and calculate y as

 $Y = y_c + or - sqrt(r_2 - (x_c - r)_2)$ 

Problem in this approach

- 1. Involves more calculations at each step.
- 2. Spacing between plotted pixel position is not uniform.

To eliminate unequal spaces by polar coordinate as

 $x = x_c + rcos\theta$ 

 $y = y_c + rsin\theta$ 

when a display is generated with these equations using a fixed angular step size, a circle is plotted with equally spaced points along the circumference.  $\theta$  depends on the application and display device.

Shape of the circle is similar in each quadrant. One quadrant are symmetric with respect

to the 45°

More efficient circle algorithm are based on incremental calculation of decision parameter.

## KARPAGAM

COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

Bresenhams algorithm method for direct distance comparison to test the halfway position between the two pixel to determine this midpoint is inside or outside the circle boundary.

Circle function for calculating mid point is  $f_{circle}(x,y) = x^2 + y^2 - r^2$ 

 $F_{circle}(x,y)$ 

<0 if (x,y) is inside the circle boundary.

=0 if(x,y) is on the circle boundary

>0 if(x,y) is outside the boundary.

Let we consider circle start position (x0,y0)=(0,r).

$$P_0 = f_{circle}(1, r-1/2)$$

$$P_0 = 5/4 - r$$

 $P_0 = 1 - r.$ 

#### **Midpoint Circle Algorithm**

• Input radius r and circle center (x<sub>c</sub>,y<sub>c</sub>), and obtain the first point on the circumference of a circle centered on the origin as

 $(x_0, y_0) = (0, r)$ 

• Calculate the initial value of the decision parameter as

 $p_0 = 5/4 - r$ 

• At each  $x_k$ , position, starting at k = 0, perform the following test : If  $p_k < 0$ , the next point along the circle centered on (0,0) is ( $x_{k+1}$ ,  $y_k$ ) and

$$p_{k+1} = p_k + 2x_{k+1} + 1$$

Otherwise, the next point along the circle is (xk + 1, yk - 1) and

$$p_{k+1} = p_k + 2x_{k+1} + 1 - 2y_{k+1}$$

Where  $2x_{k+1} = 2x_k + 2$  and  $2y_{k+1} = 2y_k - 2$ .

- Determine symmetry points in the other seven octants.
- Move each calculated pixel position (x,y) onto the circular path centered on (x<sub>c</sub>, y<sub>c</sub>) and plot the coordinate values:

$$\mathbf{x} = \mathbf{x} + \mathbf{x}_{c} , \mathbf{y} = \mathbf{y} + \mathbf{y}_{c}$$

• Repeat steps 3 through 5 until x >= y;

#### POLYGON FILLING ALGORITHM

Polygon is an ordered list of vertices as shown in the following figure. For filling polygons with particular colors, you need to determine the pixels falling on the border of the polygon and those which fall inside the polygon. In this chapter, we will see how we can fill polygons using different techniques.

This algorithm works by intersecting scanline with polygon edges and fills the polygon between pairs of intersections. The following steps depict how this algorithm works.

**Step 1** – Find out the Ymin and Ymax from the given polygon.

**Step 2** – ScanLine intersects with each edge of the polygon from Ymin to Ymax. Name each intersection point of the polygon. As per the figure shown above, they are named as p0, p1, p2, p3.

**Step 3** – Sort the intersection point in the increasing order of X coordinate i.e. (p0, p1), (p1, p2), and **Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE** 30/33

#### ANTIALIASING

Antialiasing is a technique used in digital imaging to reduce the visual defects that occur when high-resolution images are presented in a lower resolution. Aliasing manifests itself as jagged or stair-stepped lines (otherwise known as jaggies) on edges and objects that should otherwise be smooth.

Antialiasing makes these curved or slanting lines smooth again by adding a slight discoloration to the edges of the line or object, causing the jagged edges to blur and melt together. If the image is zoomed out a bit, the human eye can no longer notice the slight discoloration that antialiasing creates.

#### UNIT III

UNIT: III

#### **SYLLABUS**

Two Dimensional Geometric Transformations: Basic Transformations: Translation – Rotation – Scaling - Composite Transformations: Translations – Rotations - Scalings. General Pivot Point Rotation - General Fixed Point Scaling. Two – Dimensional Viewing: The Viewing Pipeline -Window to viewport Transformation - Clipping Operations: Point Clipping - Line Clipping Algorithms- Cohen Sutherland Line Clipping - Polygon Clipping: Sutherland – Hodgeman Polygon Clipping Algorithm - Text Clipping

#### TWO DIMENSIONAL GEOMETRIC TRANSFORMATIONS:

#### BASIC TRANSFORMATION:

- 1. TRANSLATION.
- 2. ROTATION.
- 3. SCALING.

#### 1. TRANSLATION: -

- It is applied to an object by repositioning it along a straight line from one coordinate location to another.
- We translate a 2-D point by adding translation distances, tx & ty to the original coordinate position (x, y) to move the point to a new position (x', y').

• 
$$x' = x + tx & y' = y + ty.$$

- The translation distance pair (tx, ty) is called a Translation vector or Shift vector.
- Translation equations as a single matrix equations by column vectors represent the coordinates:

$$P' = P + T. \rightarrow (1)$$

• Where 
$$\mathbf{P} = \begin{bmatrix} x1 \\ x2 \end{bmatrix}$$
,  $\mathbf{P}^{*} = \begin{bmatrix} x1' \\ x2' \end{bmatrix}$ ,  $\mathbf{T} = \begin{bmatrix} tx \\ ty \end{bmatrix}$ 

• In terms of coordinate row vectors :

$$\mathbf{P} = \begin{bmatrix} x, y \end{bmatrix} \& \mathbf{T} = \begin{bmatrix} tx, ty \end{bmatrix}$$

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE

1/23

- Translation is a Rigid-body transformation\_that moves object without deformation.
- A straight-line segment is translated by applying the transformation equation (1) to each of the line endpoints and redraws the line between the new endpoint positions.
- Polygons are translated by adding the translating vector to the coordinate position of each vertex and regenerating the polygons using the new set of vertex coordinates.
- To change the position of a circle or ellipse we translate the center coordinates and redraw the figure in the new location.
- If tx, ty value is higher than the width value then there will be an error [Wraparound].

#### 2. <u>ROTATION:</u>

- A 2-D rotation is applied to an object by repositioning it along a circular path in the XY plane.
- To generate a rotation specify a rotation point (or) pivot point about which the object is to be rotated.
- Positive values for rotation angle define counterclockwise rotation about the pivot point.
- Negative values rotate object in the clockwise direction.
- This transformation can also be described as a rotation about a rotation axis that is perpendicular to the XY plane and passes through the pivot point.
  - 1. The transformation equation for rotation of a point position P when the pivot point is at the coordinate origin:

#### COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

Figure shows the angular and coordinate relationships of the original and transformed point positions:

• In the figure r is the constant distance of the point from the origin.

**UNIT: III** 

- Angle  $\Phi$  is the original angular position of the point from the horizontal.
- $\Theta$  is the rotation angle.
- By using the trigonometric identities;

adj  $\cos \Theta = hyp$ opp  $\sin \Theta$ = hypopp  $\tan \Theta = adj$  $X = r \cos \Phi \rightarrow (1)$  $Y = r \sin \Phi \rightarrow (2)$  $X' = r \cos (\Phi + \Theta) \rightarrow (3)$ 

#### 2. Rotation of a point about an arbitrary pivot position:

 $Y' = r \sin (\Phi + \Theta) \rightarrow 4)$ 

Objects can be rotated about an arbitrary point by modifying the equation (7) to include the coordinates (xr, yr) for the selected rotation point.

• The transformation equations for the rotated coordinates are obtained by the trigonometric relationship.

$$X' = xr + (x - xr) \cos\Theta - (y - yr) \sin\Theta$$

$$Y' = yr + (x - xr)\sin\Theta + (y - yr)\cos\Theta$$

• Every point on an object is rotated through the same angle.

UNIT: III

#### CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

- 3. SCALING:
  - Scaling transformation alters the size of an object.
  - For polygon the scaling can be carried out by multiplying the coordinate values (x , y) of each vertex by scaling factors sx & sy to produce the transformed coordinates (x', y'):

$$\mathbf{x}' = \mathbf{x}.\mathbf{s}\mathbf{x} \quad \& \quad \mathbf{y}' = \mathbf{y}.\mathbf{s}\mathbf{y} \rightarrow (1)$$

- Scaling factors sx scales object in the x-direction & sy in the y-direction.
- Transformation equation in the matrix form :

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} sx & 0 \\ 0 & sy \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$
$$\mathbf{n}' = \mathbf{s} \mathbf{n}$$

- Any positive values can be assigned to the scaling factors sx & sy.
- Sx & sy values less than 1 reduce the size of objects.
- Values greater than 1 produces enlarged object.
- Value of sx & sy is 1 means leaves the size of objects unchanged.
- When sx & sy are of same value a uniform scaling is produced.
- Unequal values for sx & sy results in a differential scaling.
- We can control the location of a scaled object by choosing a position called the fixed point, which remains unchanged after the scaling transformation.
- Scaling relative to a chosen fixed point ( xf , yf) is:

$$\begin{cases} X = xf + (x - xf). Sx \\ y = yf + (y - yf). sy \end{cases} \rightarrow (3)$$

$$\begin{cases} x' = x.sx + (1 - sx).xf \\ y' = y.sy + (1 - sy).yf \end{cases}$$

(3) Same as

#### MATRIX REPRESENTATIONS & HOMOGENEOUS COORDINATES:

To express any 2-D transformation as a matrix multiplication we represent each Cartesian • coordinate position (x, y) with the homogeneous coordinate triple (xh, yh, h) where X=

$$\frac{xh}{h}$$
  $Y=\frac{yh}{h}$ 

- Homogeneous coordinate can also be represent as (xh, yh, h). •
- For 2-D geometric transformation we choose the homogeneous parameter h to be any non-• zero value.
- For 2-D homogeneous coordinates (x, y, 1).
- Other values for parameter h are needed for 3-D viewing transformation.

1

#### For translation transformation:

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix}_{=} \begin{bmatrix} 1 & 0 & tx \\ 0 & 1 & ty \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$
P'=T (x, y). P  
X'=x + tx  
Y'=y + ty  
1=1

#### **For Rotation Transformation:**

$$\begin{bmatrix} x' \\ y' \\ 1 \end{bmatrix}_{=} \begin{bmatrix} \cos \theta & -\sin \theta & 0 \\ \sin \theta & \cos \theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ 1 \end{bmatrix}$$
$$P'=R(\theta). P$$
$$X'=x. \cos \theta - y. \sin \theta$$
$$Y'=y \cos \theta + x. \sin \theta$$

**For Scaling Transformation:**

### CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B UNIT: III

#### COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

#### 4. General Pivot-Point Rotation:

- Rotation about any selected pivot-point (x, y) by performing translation-rotation-translation.
- <u>Steps:</u>
  - a) Translate the object so that the pivot point position is moved to the coordinate origin.
  - b) Rotate the object about the coordinate origin.
  - c) Translate the object so that the pivot point is returned to its original position.

#### 5. <u>General Fixed Point Scaling:</u>

- a) Translate objects so that the fixed point coincides with the coordinate origin.
- b) Scale the object with respect to the coordinate origin.
- c) Use the inverse translation of step1 to return to the original position.

#### TWO DIMENSIONAL VIEWING

We now consider the formal mechanism for displaying views of a picture on an output device. Typically, a graphics package allows a user to specify which part of a defined picture is to be display& and where that part is to be placed on the display device. Any convenient Cartesian coordinate system, referred to as the world-coordinate reference frame, can be used to define the picture. For a two-dimensional picture, a view is selected by specifying a sub area of the total picture area. A user can select a single area for display, or several areas could be selected for simultaneous display or for an animated panning sequence across a scene. The picture parts within the selected areas are then mapped onto specified areas of the device coordinates. When multiple view areas are selected, these areas can be placed in separate display locations, or some areas could be inserted into other, larger display areas. Transformations from world to device coordinates involve translation, rotation, and scaling operations, as well as procedures for deleting those parts of the picture that are outside the limits of a selected display area.

#### THE VIEWING PIPELINE (

A world-coordinate area selected for display is called a window. An area on a display device to which a window is mapped is called a view port. The window defines what is to be viewed; the view port defines where it is to be displayed. Often, windows and view ports are rectangles in standard position, with the rectangle edges parallel to the coordinate axes. Other window or view port geometries, such as general polygon shapes and circles, are used in some applications, but these shapes take longer to process. In general, the mapping of a part of a world-coordinate scene to device coordinates is referred to as a viewing transformation. Sometimes the two-dimensional viewing transformation is simply referred to as the window-to-view port transformation or the windowing transformation. But, in general, viewing involves more than just the transformation from the window to the view port. Figure1 illustrates the mapping of a picture section that falls within a rectangular window onto a designated & angular view port.

In computer graphics terminology, the term window originally referred to an area of a picture that is selected for viewing, as defined at the beginning of this section. Unfortunately, the same tern is now used in window-manager systems to refer to any rectangular screen area that can be moved about,

#### CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

#### COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

resized, and made active or inactive. In this chapter, we will only use the term window to refer to an area of a world-coordinate scene that has been selected for display.

UNIT: III

A viewing transformation using standard rectangle for the windows and view port.

Some graphics packages that provide window and view port operations allow only standard rectangles, but a more general approach is to allow the rectangular window to haw any orientation.

# In this case, we carry out the viewing transformation in several steps, as indicated in Figure First, we construct the scene in world coordinates using the output primitives and attributes. Next. to obtain a particular orientation for the window, we can set up a two-dimensional viewing-coordinate system in the world-coordinate plane, and define a window In the viewing-coordinate system. The viewing

## CLASS: III B.SC MATHEMATICSCOURSE NAME: COMPUTER GRPHICSCOURSE CODE: 16MMU503BUNIT: IIIBATCH: 2016-2019

coordinate reference frame is used to provide a method for setting up arbitrary orientations for rectangular windows. Once the viewing reference frame is established, we can transform descriptions in world coordinates to viewing coordinates. We then define a view port in normalized coordinates (in the range from 0 to 1) and map the viewing-coordinate description of the scene to normalized coordinates. At the final step, .all parts of the picture that he outside the view port are clipped, and the contents of the view port are transferred to device coordinates. Figure, illustratt.s a rotated viewing-coordinate reference frame and the mapping to normalized coordinates.

Setting up rotated world windows in viewing coordinates and the corresponding normalized – coordinate view port.

By changing the position of the view port, we can view objects at different positions on the display area of an output device. Also, by varying the size of view ports, we can change the size and proportions of displayed objects. We achieve zooming effects by successively mapping different-sized windows on a fixed-size view port. As the windows are made smaller, we zoom in on some part of a scene to view details that are not shown with larger windows. Similarly, more overview is obtained by zooming out from a section of a scene with successively larger windows. Panning effects are produced by moving a fixed-size window across the various objects in a scene.

View ports are typically defined within the unit square (normalized coordinates). This provides a means for separating the viewing and other transformations from specific output-device requirements, so that the graphics package is largely device-independent. Once the scene has been

transferred to normalized coordinates, the unit square is simply mapped to the display area for the particular output device in use at that time. Different output devices can be used by providing the appropriate device drivers.

#### WINDOWS TO VIEW PORT COORDINATE TRANSFORMATION.

Once object descriptions have been transferred to the viewing reference frame, we choose the window extents in viewing limits in normalized coordinates. Object descriptions are then transferred to normalized device coordinates. We do this using a transformation that maintains the same relative placement of objects in normalized space as they had in viewing coordinates. If a coordinate position is at the center of the viewing window, for instance, it will be displayed at the center of the view port.

Figure4 illustrates the window-to-view port mapping. A point at position (xw, yw) in the window 1s mapped into position (xv, yv) in the associated view port. To maintain the same relative placement in the view port as in the window, we require that

$$\frac{xv - xv_{\min}}{xv_{\max} - xv_{\min}} = \frac{xw - xw_{\min}}{xw_{\max} - xw_{\min}}$$
$$\frac{yv - yv_{\min}}{yv_{\max} - yv_{\min}} = \frac{yw - yw_{\min}}{yw_{\max} - yw_{\min}}$$

Fig4: A point at position (xw, yw) in redesigned windows is mapped to view port coordinates (xv, yv) so that relative position in the two areas are the same.

Solving these expressions for the view port position (xv, yv), we have

$$xv = xv_{\min} + (xw - xw_{\min})sx$$
$$yv = yv_{\min} + (yw - yw_{\min})sy$$

where the scaling factors are

$$sx = \frac{xv_{\max} - xv_{\min}}{xw_{\max} - xw_{\min}}$$
$$sy = \frac{yv_{\max} - yv_{\min}}{yw_{\max} - yw_{\min}}$$

Equations can also be derived with a set of transformations that converts the window area into the view port area. This conversion is performed with the following sequence of transformations:

1. Perform a scaling transformation using a fixed-point position of  $(xw_{min}, yw_{min})$  that scales the window area to the size of the view pot.

2. Translate the scaled window area to the position of the view port.

Relative proportions of objects are maintained if the scaling factors are the same (sx = sy). Otherwise, world objects will be stretched or contracted in either the x or y direction when displayed on the output device.

Character strings can be handled in two ways when they are mapped to a view port. The simplest mapping maintains a constant character size, even though the view port area may be enlarged or

reduced relative to the window. This method would be employed when text is formed with standard character fonts that cannot be changed. In systems that allow for changes in character size, string definitions can be windowed the same as other primitives. For characters formed with line segments, the mapping to the view port can be carried out as a sequence of line transformations.

From normalized coordinates, object descriptions are mapped to the various display devices. Any number of output devices can be open in a particular application, and another window-to-view port transformation can be performed for each open output device. This mapping, called the workstation transformation, IS accomplished by selecting a window area in normalized space and a view port area in the coordinates of the display device. With the workstation transformation, we gain some additional control over the positioning of parts of a scene on individual output devices. **As** illustrated in Fig.5, we can use workstation transformations to partition a view so that different parts of normalized space can be displayed on different output devices.

Mapping selected parts of a scene in normalized coordinates to different video monitors with workstation transformations.

#### **CLIPPING OPERATION**

## CLASS: III B.SC MATHEMATICSCOURSE NAME: COMPUTER GRPHICSCOURSE CODE: 16MMU503BUNIT: IIIBATCH: 2016-2019

Generally, any procedure that identifies those portions of a picture that are either inside or outside of a specified region of space is referred to as a clipping algorithm, or simply clipping. The region against which an object is to clipped is called a clip window.

Applications of clipping include extracting part of a defined scene for viewing; identifying visible surfaces in three-dimensional views; anti aliasing line *seg*ments or object boundaries; creating objects using solid-modeling procedures;

Displaying a multi window environment; and drawing and painting operations that allow parts of a picture to be selected for copying, moving, erasing, or duplicating. Depending on the application, the clip window can be a general polygon or it can even have curved boundaries. We first consider clipping methods using rectangular clip regions, then we discuss methods for other clip region shapes.

In the following sections, we consider algorithms for clipping the following primitive types

- Point Clipping
- Line Clipping (straight-line segments)
- Area Clipping (polygons)
- Curve Clipping
- Text Clipping

Line and polygon clipping routines are standard components of graphics packages, but many packages accommodate curved objects, particularly spline curves and conics, such as circles and ellipses. Another way to handle curved objects is to approximate them with straight-line segments and apply the line or polygon clipping procedure.

#### **Point clipping**

Assuming that the clip window is a rectangle in standard position, we save a point P = (x, y) for display if the following inequalities are satisfied:

**UNIT: III** 

#### CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

 $xw_{\min} \le x \le xw_{\max}$ 

 $yw_{\min} \le y \le yw_{\max}$ 

where the edges of the clip window  $(xw_{min}, xw_{max}, yw_{min}, yw_{max})$  can be either the worldcoordinate window boundaries or view port boundaries. If any one of these four inequalities is not satisfied, the point is clipped (not saved for display). Although point clipping is applied less often than line or polygon clipping, some .applications may require a point clipping procedure. For example, point clipping can be applied to scenes involving explosions or sea foam that are modeled with particles (points) distributed in some region of the scene.

#### Line clipping

The relationships between line positions and a standard rectangular clipping region. A line clipping procedure involves several parts. First, we can test a given line segment to determine whether it lies completely inside the clipping window. If it does not, we try to determine whether it lies completely outside the window. Finally, if we cannot identify a line as completely inside or completely outside, we must perform intersection calculations with one or more clipping boundaries. We process lines through the "inside-outside" tests by checking the line endpoints. A line with both endpoints inside all clipping boundaries, such as the line from  $P_1$  to  $P_2$ , is saved. A line with both endpoints outside any one of the clip boundaries (line  $\overline{P_3P_4}$  in Figure) is outside the window.

COURSE NAME: COMPUTER GRPHICS UNIT: III BATCH: 2016-2019

All other lines cross one or more clipping boundaries, and may require calculation of multiple intersection points. to minimize calculations, we try to devise clipping algorithms that can efficiently identify outside lines and reduce intersection calculations.

For a line segment with endpoints  $(x_1,y_1)$  and  $(x_2,y_2)$  and one or both endpoints outside the clipping rectangle, the parametric representation.

 $X = x_v + u(x_2 - x_1)$ Y = y\_v + u(y\_2 - y\_1) 0 < u < 1

UNIT: III

Could be used to determine values of parameter **u** for intersections with the clipping boundary coordinates. If the value of u for an intersection with a rectangle boundary edge is outside the range 0 to 1, the line does not enter the interior of the window at that boundary. If the value of u is with in the range from 0 to 1, the line segment does indeed cross into the clipping area. This method can be applied to each clipping boundary edge in turn to determine whether any part of the line segment is to be displayed. Line segments that are parallel to window edges can be handled as special cases.

Clipping line segments with these parametric tests requires a good deal of

Computation and faster approaches to clipping are possible. A number of efficient line clippers have been developed, and we survey the major algorithms in the next section. Some algorithm are designed explicitly for two-dimensional

Pictures and some are easily adapted to three-dimensional applications.

#### **Cohen-Sutherland line clipping**

This is one of the oldest and most popular line-clipping procedures. Generally, the method speeds up the processing of line segments performing initial tests that reduce the number of intersections that must he calculated. Every line end Point in a picture is assigned a four-digit binary code, called a region code that identifies the location of the point relative to the boundaries of the clipping rectangle. Regions are set up in reference to the boundaries as shown in Fig.7. Each bit position in the region code is used to indicate one of the four relative coordinate positions of the point with respect to the clip window: to the left, right, top, or bottom. By numbering the bit positions in the region code as 1 through 4 from right to left, the coordinate regions can be correlated with the bit positions as

bit 1: left

#### bit 2: right

**UNIT: III** 

#### CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

bit 3: below

bit 4: above

Binary region codes assigned to line endpoints according to relative position with respect to the clipping rectangle.

A value of 1 in any bit position indicates that the point is in that relative position; Otherwise, the bit position is set to 0. If a point is within the clipping rectangle, the region code is 0000. A point that is below and to the left of the rectangle has a region code of 0101. Bit values in the region code are determined by comparing endpoint Coordinate values (x, y) to the clip boundaries. Bit 1 is set to 1 if  $x < xw_{min}$ , The other three bit values can be determined using similar comparisons. For languages in which bit manipulation is possible, region-code bit values can be determined with the following two steps: (1) Calculate differences between endpoint coordinates and clipping boundaries. (2) Use the resultant sign bit of each difference calculation to set the corresponding value in the region code. Bit 1 is the sign bit of x - bit 2 is the sign bit of  $xw_{max} - x$ ; bit 3 is the sign bit of  $y - yw_{min}$ ; and bit 4 is the sign bit of  $yw_{max} - y$ .

## CLASS: III B.SC MATHEMATICSCOURSE NAME: COMPUTER GRPHICSCOURSE CODE: 16MMU503BUNIT: IIIBATCH: 2016-2019

Once we have established region codes for all line endpoints, we can quickly determine which lines are completely inside the clip window and which are clearly outside. Any lines that are completely contained within the window boundaries have a region code of 0000 for both endpoints, and we trivially accept these lines. Any lines that have a 1 in the same bit position in the region codes for each endpoint are completely outside the clipping rectangle, and we trivially reject these lines. We would discard the line that has a region code of 1001 for one endpoint and a code of 0101 for the other endpoint. Both endpoints of this line are left of the clipping rectangle, as indicated by the 1 in the first bit position of each region code. A method that can be used to test lines for total clipping is to perform the logical and operation with both region codes. If the result is not 0000, the line is completely outside the clipping region.

Lines that cannot be identified as completely inside or completely outside a Clip window by these tests are checked for intersection with the window boundaries. As shown in Fig.8, such lines may or may not cross into the window interior. We begin the clipping process for a line by comparing an outside endpoint to a clipping boundary to determine how much of the line can be discarded. Then the remaining part of the Line is checked against the other boundaries, and we continue until either the line is totally discarded or a section is found inside the window. We set up our algorithm to check line endpoints against clipping boundaries in the order left, right, bottom, top.

Lines extending from one coordinate region to another may pass through the clip window, or they may intersect clipping boundaries without entering the window.

To illustrate the specific steps in clipping lines against rectangular boundaries using the Cohen-Sutherland algorithm, we show how the lines in Figure could be processed. Starting with the bottom endpoint of the line from  $P_1$  to  $P_2$ 

We check P, against the left, right, and bottom boundaries in turn and find that this point is below the clipping rectangle. We then find the intersection point Pi with the bottom boundary and discard the line section from  $P_1$  to  $P_1$ . The line now has been reduced to the section from  $P_1$  to  $P_2$  is outside the clip window, we check this endpoint against the boundaries and find that it is to the left of the window. Intersection point  $P_2$  is calculated, but this point is above the window. So the final intersection calculation yields  $P_2$  and the line from  $P_1$  to  $P_2$  is saved. This completes processing for this line, so we save this part and go on to the next line. Point  $P_3$  in the next line is to the left of the clipping rectangle, so we determine the intersection  $P_3$  and eliminate the line section from  $P_3$  to  $P_3$  By checking region codes for the line section from  $P_3$  to  $P_4$  we find that the remainder of the line is below the clip window and can be discarded also.

Intersection points with a clipping boundary can be calculated using the

Slope-intercept form of the line equation. For a line with endpoint coordinates (x,y) and (x2, y2), they coordinate of the intersection point with a vertical boundary can be obtained with the calculation.

#### $Y=y_1+m(x-x_1)$

where the x value is set either to  $xw_{min}$  to  $xw_{max}$  and the slope of the line is calculated as m=(y2-y1)/(x2-x1).Similarly, if we are looking for the intersection with a horizontal boundary, the x coordinate can be calculated as

$$x = x_1 + \frac{y - y_1}{m}$$

with y set either to  $yw_{min}$  or to  $yw_{max}$

#### CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

#### **Polygon clipping**

To clip polygons, we need to modify the line-clipping procedures discussed in the previous section. A polygon boundary processed with a line clipper may be displayed as a series of unconnected line segments Figure depending on the Orientation of the polygon to the clipping window.

Display of a polygon processed by a line-dipping algorithm

What we really want to display is a bounded area after clipping, as in Figure. For polygon clipping, we require an algorithm that will generate one or more closed areas that are then scan converted for the appropriate area fill. The output of a polygon clipper should be a sequence of vertices that defines the clipped polygon boundaries.

#### Sutherland-Hodgeman polygon clipping

We can correctly clip a polygon by processing the polygon boundary as a whole against each window edge. This could be accomplished by processing all polygon vertices against each clip rectangle boundary in turn. Beginning with the initial set of polygon vertices, we could first clip the polygon against the left rectangle boundary to produce a new sequence of vertices. The new set of vertices could then k successively passed to a right boundary clipper, a bottom boundary clipper, and a top boundary clipper, as in Fig.11. At each step, a new sequence of output vertices is generated and passed to the next window boundary clipper.

Clipping a polygon against successive window boundaries.

UNIT: III

#### CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

#### COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

There are four possible cases when processing vertices in sequence around the perimeter of a polygon. As each pair of adjacent polygon vertices is passed to a window boundary clipper, we make the following tests: (1) If the first vertex is Outside the window boundary and the second vertex is inside, both the intersection point of the polygon edge with the window boundary and the second vertex are added to the output vertex list. (2) If both input vertices are inside the window boundary, only the second vertex is added to the output vertex list. (3) if the first vertex is inside the window boundary is added to the output vertex is outside, only the edge intersection with the window boundary is added to the output vertex list. (4) If both input vertices are outside the window boundary, nothing is added to the output list. These four cases are illustrated in Figure for successive pairs of polygon vertices. Once all vertices have been processed for one clip window boundary; the output list of vertices is clipped against the next window boundary.

Successive processing of pairs of polygon vertices against the left window boundary.

#### Text clipping

There are several techniques that can be used to provide text clipping in a graphics package. The clipping technique used will depend on the methods used to generate characters and the requirements of a particular application.

The simplest method for processing character strings relative to a window boundary is to use the all-or-none string-clipping strategy shown in Fig.13. If all of the string is inside a clip window, we keep it. Otherwise, the string is discarded. This procedure is implemented by considering a bounding rectangle around the text pattern. The boundary positions of the rectangle are then compared to the window boundaries, and the string is rejected if there is any overlap. This method produces the fastest text clipping.

An alternative to rejecting an entire character string that overlaps a window

boundary is to use the all-or-none character-clipping strategy. Here we discard only those characters that are not completely inside the window. In this case, the boundary limits of individual characters are compared to the window. Any character that either overlaps or is outside a window boundary is clipped.

UNIT: III

#### COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019

Text clipping using a bounding & tangle about individual characters

A final method for handling text clipping is to clip the components of individual Characters. We now treat characters in much the same way that we treated lines. If an individual character overlaps a clip window boundary, we clip off the Parts of the character that are outside the window Outline character Fonts formed with line segments can be processed in this way using a line clipping algorithm. Characters defined with bit maps would be clipped by comparing the relative position of the individual pixels in the character grid patterns to the clipping boundaries.

#### **POSSIBLE QUESTIONS**

UNIT: III

#### UNIT III

#### PART-A (20 Marks)

#### (Q.No 1 to 20 Online Examination)

#### PART-B (2 Marks)

- 1.Define Translation.
- 2.Define Rotation.
- 3.Define Scaling.
- 4. State the different clipping operations available.
- 5.Define Line clipping
- 6.Define Text clipping

#### PART-C (6 Marks)

- 1. Explain the Composite transformation?
- 2. Briefly explain Basic transformations?
- 3. Explain briefly about the other transformations?
- 4. Write in detail on clipping for point, line, and polygon Clipping
- 5. How the line clipping process happens in Cohen Sutherland Line Clipping algorithm
- 6. What is Window and View port Coordinate system and how the transformations are performed
- 7. Write the algorithm of Sutherland Hodgeman Polygon Clipping and explain it with example.
- 8. Explain the method of transforming the co-ordinates from window to View port
- 9. Explain in detail about clipping operation functions
- 10. Illustrate about Two Dimensional Viewing with suitable diagrams
- 11. Discuss about point clipping and line clipping in detail
- 12. How the polygon clipping process takes place in Sutherland-Hodgman polygon clipping algorithm

# UNIT IV

# SYLLABUS

Three – Dimensional Display methods, Three – Dimensional Transformations : Translation – Rotation – Scaling, Three Dimensional viewing : Viewing pipeline -Viewing coordinates - Parallel Projection – . Perspective Projections

#### Introduction

When we model and display a three-dimensional scene, there are many more considerations we must take into account besides just including coordinate values for the third dimension. Object boundaries can be constructed with various combinations of plane and curved surfaces, and we sometimes specify information about object interiors. Graphics packages often provide routines for displaying internal components or cross-sectional views of solid objects. Also, some geometric transformations are more involved in three-dimensional space than in two dimensions.

For example, we can rotate an object about an axis with any spatial orientation in threedimensional space. Two-dimensional rotations, on the other hand, are always around an axis that is perpendicular to the xy plane. Viewing transformations in three dimensions are much more complicated because we have many more parameters to select when specifying how a three-dimensional scene is to be mapped to a display device. The scene description must be processed through viewing-coordinate transformations and projection routines that transform three-dimensional viewing coordinates onto two-dimensional device coordinates. Visible parts of a scene; for a selected view, must he identified; and surface-rendering algorithms must he applied if a realistic rendering of the scene is required.

## COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

#### Three dimensional display methods

To obtain a display of a three-dimensional scene that has been modeled in world coordinates. We must first set up a coordinate reference for the "camera". This coordinate reference defines the position and orientation for the plane on the camera film Figure, which is the plane we want to use to display a view of the objects in the scene. Object descriptions are then transferred to the camera reference coordinates and projected onto the selected display plane. We can then display the objects in wire frame (outline) form; we can apply lighting and surface rendering techniques to shade the visible surfaces.

Coordinate reference for obtaining a particular view of a three dimensional scene

#### COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

#### **Three Dimensional Geometric Transformations**

Methods for geometric transformations and object modeling in three dimensions are extended from two-dimensional methods by including considerations for the z coordinate. We now translate an object by specifying a three-dimensional translation vector, which determines how much the object is to be moved in each of the three coordinate directions. Similarly, we scale an object with three coordinate scaling factors. The extension for three-dimensional rotation is less straightforward. When we discussed two-dimensional rotations in the xy plane, we needed to consider only rotations about axes that were perpendicular to the xy plane. In three-dimensional space, we can now select any spatial orientation for three rotations, one for each of the three Cartesian axes. Alternatively, a user can easily set up a general rotation matrix, given the orientation of the axis and the quired rotation angle. As in the two-dimensional case, we express geometric transformations in matrix form. Any sequence of transformations is then represented as, a single matrix, formed by concatenating the matrices for the individual transformations in the sequence.

#### Translation

In a three-dimensional homogeneous coordinate representation, a point is translated from position P = (x, y, z) to position P' = (x', y', z') with the matrix operation

$$\begin{bmatrix} x' \\ y' \\ z' \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & t_x \\ 0 & 1 & 0 & t_y \\ 0 & 0 & 1 & t_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix}$$
Or
$$P' = \mathbf{T} \cdot \mathbf{P}$$

# COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

Parameters  $t_x$ ,  $t_y$ , and  $t_z$ , specifying translation distances for the coordinate directions x, y, and z, are assigned any real values. The matrix representation is equivalent to the three equations,

Translating a point with translation vector  $\mathbf{T} = (t_x, t_y, t_z)$ .

An object is translated in three dimensions by transforming each of the defining points of the object. For an object represented as a set of polygon surfaces, we translate each vertex of each surface Figure and redraw the polygon facets in the new position.

#### COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

#### Translating an object with translation vector T.

We obtain the inverse of the translation matrix in Eq. 11-1 by negating the translation distances  $t_x$ ,  $t_y$  and  $t_z$  this produces a translation in the opposite direction, and the product of a translation matrix and its inverse produces the identity Matrix.

#### Rotation

To generate a rotation transformation for an object, we must designate an axis of rotation (about which the object is to be rotated) and the amount of angular rotation. Unlike twodimensional applications, where all transformations are carried

out in the xy plane, a three-dimensional rotation can be specified around any line in space. The easiest rotation axes to handle are those that are parallel to the coordinate axes. Also, we can use combinations of coordinate axis rotations (along with appropriate translations) to specify any general rotation.

By convention, positive rotation angles produce counterclockwise rotations about a coordinate axis, if we are looking along the positive half of the axis toward the coordinate origin Figure. This agrees with our earlier discussion of Rotation in two dimensions, where positive rotations in the xy plane are counterclockwise about axes parallel to the z axis.

# COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

Fig3: Positive rotation directions about the coordinate axes are Counterclockwise, when looking toward the origin from a positive coordinate position on each axis.

The two-dimensional z-axis rotation equations are easily extended to three dimensions:

$$x' = x \cos \theta - y \sin \theta$$
$$y' = x \sin \theta + y \cos \theta$$
$$z' = z$$

# COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

Parameter  $\theta$  specifies the rotation angle. In homogeneous coordinate form, the threedimensional z-axis rotation equations are expressed as,

| [x]        | 1 | cesθ          | $-\sin\theta$ | 0 | 07 | $\begin{bmatrix} x \end{bmatrix}$ |
|------------|---|---------------|---------------|---|----|-----------------------------------|
| <i>y</i> ′ |   | $\sin \theta$ | cosθ          | 0 | 0  | v                                 |
| $z^{i}$    | - | Ø             | 0             | 1 | 0  | 1                                 |
| LIJ.       |   | 0             | 0             | 0 | 1] |                                   |

which we can write more compactly as,

$$\mathbf{P'} \simeq \mathbf{R}_{\mathbf{z}}(\theta) \cdot \mathbf{F}$$

Figure illustrates rotation of an object about the z axis.

Rotation of an object about the z axis

Transformation equations for rotations about the other two coordinate axes can be obtained with a cyclic permutation of the coordinate parameters x, y, and z in Eqs. 11-4. That is, we use the replacements

 $x \rightarrow y \rightarrow z \rightarrow x$ 

as illustrated in Figure.

Substituting permutations, we get the equations for an x-axis rotation:

#### COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

 $y' = y \cos \theta - z \sin \theta$  $z' = y \sin \theta + z \cos \theta$ x' = x

which can be written in the homogeneous coordinate form

Cyclic permutation of the Cartesian-coordinate axes to produce the three sets of coordinate-axis rotation equations.

Cyclically permuting coordinates give us the transformation equations for a y-axis rotation:

 $z' = z \cos \theta - x \sin \theta$  $x' = z \sin \theta + x \cos \theta$ y' = y

The matrix representation for y-axis rotation is

#### KARPAGAM ACADEMY OF HIGHER EDUCATION

Rotation of an object about the y axis.

An inverse rotation matrix is formed by replacing the rotation angle 0 by  $-\theta$ . Negative values for rotation angles generate rotations in a clockwise direction, so the identity matrix is produced when any rotation matrix is multiplied by its inverse. Since only the sine function is affected by the change in sign of the rotation angle, the inverse matrix can also be obtained by interchanging rows and columns. That is, we can calculate the inverse of any rotation matrix R by evaluating its transpose  $(\mathbf{R}^{-1} = \mathbf{R}^{T})$ . This method for obtaining an inverse matrix holds also for any composite rotation matrix.

# COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

#### **General Three-Dimensional Rotations**

A rotation matrix for any axis that does not coincide with a coordinate axis can be set up as a composite transformation involving combinations of translations and the coordinate-axes rotations. We obtain the required composite matrix by first setting up the transformation sequence that moves the selected rotation axis onto one of the coordinate axes. Then we set up the rotation matrix about that coordinate axis for the specified rotation angle. The last step is to obtain the inverse transformation sequence that returns the rotation axis to its original position.

In the special case where an object is to be rotated about an axis that is parallel to one of the coordinate axes, we can attain that

desired rotation with the following transformation sequence.

- 1. Translate the object so that the rotation axis coincides with the parallel coordinate axis.
- 2. Perform the specified rotation about that axis.
- 3. Translate the object so that the rotation axis is moved back to its original position.

The steps in this sequence are illustrated in Figure. Any coordinate position P on the object in this figure is transformed with the sequence shown as,

 $\mathbf{P}' = \mathbf{T}^{+1} \cdot \mathbf{R}_i(\theta) + \mathbf{T} \cdot \mathbf{P}$

COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

Original Position o' Object

(c) Rotate Object Through Angle

(d) Translate Rotation Axis to Original Position

Sequence of transformations for rotating an object about an axis that is parallel to the x axis

where the composite matrix for the transformation is,

 $\mathbf{R}(\boldsymbol{\theta}) = \mathbf{T}^{-1} \cdot \mathbf{R}_{\mathbf{a}}(\boldsymbol{\theta}) \cdot \mathbf{T}$ 

which is of the same form as the two-dimensional transformation sequence for rotation about an arbitrary pivot point.

When an object is to be rotated about an axis that **is** not parallel to one of the coordinate axes, we need to perform some additional transformations. In this case, w also need rotations lo align the axis with a selected coordinate axis and to bring the axis hack to its original orientation. Given the specifications for the rotation axis and the rotation angle, we can accomplish the required rotation in five steps.

1 Translate the object so that the rotation axis pass= through the coordinate origin.

# COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

- 2. Rotate the object so that the axis of rotation coincides with one of the coordinate axes.
- 3. Perform the specified rotation about that coordinate axis.
- 4. Apply inverse rotations to bring the rotation axis back to its original orientation.
- 5. Apply the inverse translation to bring the rotahon axis back to its original position.

#### Scaling

The matrix expression for the scaling transformation of a position P = (x, y, z) relative to the coordinate origin can be written as

Where scaling parameters  $s_{x, syandszare}$  assigned any positive values. Explicit expressions for the coordinate transformations for scaling relative to the origin are

 $x' = x \cdot s_{z}, \qquad y' = y \cdot s_{y}, \qquad z' = z \cdot s_{z}$ 

Doubling the sue of an object with transformation 11-42 also moves the object farther from the origin

Scaling an object with transformation 11-42 changes the size of the object and repositions the object relative to the coordinate origin. Also, if the transformation parameters are not all equal, relative dimensions in the object are changed: We preserve the original shape of an object with a uniform scaling  $(s_r = -s_s = s_s)$ . The result of scaling an object uniformly with each scaling parameter set to 2 is shown in Figure.

Scaling with respect to a selected fixed position  $(x_f, y_f, z_f)$  can be represented with the following transformation sequence:

- 1. Translate the fixed point to the origin.
- 2. Scale the object relative to the coordinate origin
- 3. Translate the fixed point back to its original position.

This sequence of transformations is demonstrated in Figure. The matrix representation for an arbitrary fixed-point scaling can then be expressed as the concatenation of these translate-scale-translate transformations as

$$\mathbf{T}(x_{\mu}, y_{\mu}, z_{i}) \cdot \mathbf{S}(s_{x_{i}}, s_{q_{i}}, s_{z}) \cdot \mathbf{T}(-x_{i_{i}} - y_{j_{i}} - z_{j}) = \begin{bmatrix} s_{i} & 0 & 0 & (1 - s_{i})x_{i} \\ 0 & s_{j} & 0 & (1 - s_{q})y_{j} \\ 0 & 0 & s_{i} & (1 - s_{z})z_{i} \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B COURSE NAME: COMPUTER GRPHICS BATCH: 2016-2019 Image: Course code: 16MMU503B Image: Code: 16MMU503B Imag

Scaling an object relative to the selected fixed point is equivalent to the sequence of transformations shown.

We form the inverse scaling matrix for either by replacing the scaling parameters  $s_1, s_2$  and  $s_3$  with their reciprocals. The inverse matrix generates an opposite scaling transformation, so the concatenation of any scaling matrix and its inverse produces the identity matrix.

# PROJECTIONS

#### **Parallel Projection**

One method for generating a view of a solid object is to project points on the object surface along parallel lines onto the display plane. By selecting different viewing positions, we can project visible points on the object onto the display plane to obtain different two-dimensional views of the object, as in Figure.

In a Parallel projection, parallel lines in the world-coordinate scene projected into parallel lines on the two-dimensional display plane. This technique is used in engineering and

# COURSE NAME: COMPUTER GRPHICS UNIT:IV BATCH: 2016-2019

architectural drawings to represent an object with a set of views that maintain relative proportions of the object. The appearance of the solid object can then be reconstructed from the major views.

Three parallel-projection views of an object, showing relative proportions from different viewing positions.

#### **Perspective Projection**

Another method for generating a view of a 3 dimensional scene is to project points to the display plane along converging paths. This causes objects farther from the viewing position to be displayed smaller than objects of the same size that are nearer to the viewing position. In a perspective projection, parallel lines in a scene that are not parallel to the display plane are projected into converging lines. Scenes displayed using perspective projections appear more realistic, since this is the way that our eyes and a camera lens form images. In the perspective projection view shown in Figure, parallel lines appear to converge to a distant point in the background, and distant objects appear smaller than objects closer to the viewing position.

#### **POSSIBLE QUESTIONS**

#### UNIT IV

#### PART-A (20 Marks)

#### (Q.No 1 to 20 Online Examination)

#### PART-B (2 Marks)

- 1. What is mainly required to obtain a display of a three-dimensional scene that has been modeled in world coordinates?
- 2. Give the matrix operation for Translation.
- **3.** Write the matrix operation for scaling.
- 4. Write the sequence for scaling with respective to fixed position.
- 5. Define perspective projection.

#### PART-C (6 Marks)

- 1. Discuss about various 3D Geometric Transformation display methods
- 2. What is parallel and perspective projection? Mention the differences between them with diagram.
- 3. Explain working methodology of Three Dimensional Display Methods
- 4. Explain the concept of parallel projections with an Example
- 5. Explain the following Three Dimensional Geometric Transformation
  - 1. Rotation
  - 2.Scaling
- 6. Explain in detail about Perspective Projections with the neat diagram
- 7. Explain working methodology of Three Dimensional Display Methods.
- 8. Explain the concept of parallel projections with an Example
- 9.Explain the following Three Dimensional Geometric Transformation a. Rotation b.Scaling

#### Visible Surface Detection Methods

A major consideration in the generation of realistic graphics displays is identifying those parts of a scene that are visible from a chosen viewing position. There are many approaches we can take to solve this problem, and numerous algorithms have been devised for efficient identification of visible objects for different types of applications. Some methods require more memory, some involve more processing time, and some apply only to special types of objects. Deciding upon a method for a particular application can depend on such factors as the complexity of the scene, type of objects to be displayed, available equipment, and whether static or animated displays are to be generated. The various algorithms are referred to as visible-surface detection methods. Sometimes these methods are also referred to as hidden-surface elimination methods, although there can be subtle differences between identifying visible surfaces and eliminating hidden surfaces. For wire frame displays, for example, we may not want to actually eliminate the hidden surfaces, but rather to display them with dashed boundaries or in some other way to retain information about their shape. In this chapter, we explore some of the most commonly used methods for detecting visible surfaces in a threedimensional scene.

# COURSE NAME: COMPUTER GRPHICS UNIT: V BATCH: 2016-2019

#### **Classification of Visible Surface Detection algorithm**

Visible-surface detection algorithms are broadly classified according to whether they deal with object definitions directly or with their projected images. These two approaches are called object-space methods and image-space methods, respectively.

An object-space method compares objects and parts of objects to each other within the scene definition to determine which surfaces, as a whole, we should label as visible. In an image-space algorithm, visibility is decided point by point at each pixel position on the projection plane. Most visible-surface algorithms use image-space methods, although object space methods can be used effectively to locate visible surfaces in some cases. Line display algorithms, on the other hand, generally use object-space methods to identify visible lines in wire frame displays, but many image-space visible-surface algorithms can be adapted easily to visible-line detection.

Although there are major differences in the basic approach taken by the various visible-surface detection algorithms, most use sorting and coherence methods to improve performance. Sorting is used to facilitate depth comparisons by ordering the individual surfaces in a scene according to their distance from the view plane. Coherence methods are used to take advantage of regularities in a scene. An individual scan line can be expected to contain intervals (runs) of constant pixel intensities, and scan-line patterns often change little from one line to the next. Animation frames contain changes only in the vicinity of moving objects. And constant relationships often can be established between objects and surfaces in a scene.

#### **Back Face Detection**

A fast and simple object-space method for identifying the back faces of a polyhedron is based on the "inside-outside" tests discussed in Chapter 10. A point (x, y, z) is "inside" a polygon surface with plane parameters A, B, C, and D if

$$Ax + By + Cz + D < 0$$

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE Page 2/15

# COURSE NAME: COMPUTER GRPHICS UNIT: V BATCH: 2016-2019

When an inside point is along the line of sight to the surface, the polygon must be a back face (we are inside that face and cannot see the front of it from our viewing position).

We can simplify this test by considering the normal vector N to a polygon surface, which has Cartesian components (A, B, C). In general, if V is a vector in the viewing direction from the eye (or "camera") position, as shown in Figure, then this polygon is a back face if

$$\mathbf{V} \cdot \mathbf{N} > 0$$

Furthermore, if object descriptions have been converted to projection coordinates and our viewing direction is parallel to the viewing z, axis, then  $\mathbf{V} = (0, 0, V_{\perp})$  and  $\mathbf{V} \cdot \mathbf{N} = V_{\perp}C$ 

so that we only need to consider the sign of C, the ; component of the normal vector N.

Vector V in the viewing direction and a back-face normal vector N of a polyhedron

In a right-handed viewing system with viewing direction along the negative z axis (Figure), the polygon is a back face if C < 0. Also, we cannot see any face whose normal has z component C - 0, since our viewing direction is grazing that polygon. Thus, in

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE Page 3/15

## COURSE NAME: COMPUTER GRPHICS UNIT: V BATCH: 2016-2019

general, we can label any polygon as a back face if its normal vector has a z-component value:

 $C \leq 0$ 

A polygon surface with plane parameter c<0 in a right hand viewing coordinate system is identified as a black face

Similar methods can be used in packages that employ a left-handed viewing system. In these packages, plane parameters A, B, C: and D can be calculated from polygon vertex coordinates specified in a clockwise direction (instead of the counterclockwise direction used in a right-handed system). Inequality 13-1 then remains a valid test for inside points. Also, back faces have normal vectors that point away from the viewing position and are identified by  $C \ge 0$  when the

Viewing direction is along the positive 2, axis.

By examining parameter C for the different planes defining an object, we can immediately identify all the back faces. For a single convex polyhedron, such as the pyramid in Fig. 3, this test identifies all the hidden surfaces on the object, since each surface is either completely visible or completely hidden. Also, if a scene contains only no overlapping convex polyhedral, then again all hidden surfaces are identified with the back-face method.

# CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B

#### COURSE NAME: COMPUTER GRPHICS UNIT: V BATCH: 2016-2019

View of a concave polyhedron with one face partially hidden by other faces.

For other objects, such as the concave polyhedron in Figure, more tests need to be carried out to determine whether there are additional faces that are to ally or partly obscured by other faces. And a general scene can be expected to contain overlapping objects along the line of sight. We then need to determine where the obscured objects are partially or completel.y hidden by other objects. In general, back-face removal can be expected to eliminate about half of the polygon surfaces in a scene from further visibility tests.

#### **Depth Buffer Method**

A commonly used image-space approach to detecting visible surfaces is the depth-buffer method, which compares surface depths at each pixel position on the projection plane. This procedure is also referred to as the z-buffer method, since object depth is usually measured from the view plane along the z axis of a viewing system. Each surface of a scene is processed separately, one point at a time across the surface. The method is usually applied to scenes containing only polygon surfaces, because depth values can be computed very quickly and the

method is easy to implement. But the method can be applied to no planar surfaces.

With object descriptions converted to projection coordinates, each (x, y, z) position on a polygon surface corresponds to the orthographic projection point (x, y) on the view plane. Therefore, for each pixel position (x, y) on the view

Plane, object depths can be compared by comparing z values. Figure 4, shows three surfaces at varying distances along the orthographic projection line from position (x, y) in

# CLASS: III B.SC MATHEMATICSCOURSE NAME: COMPUTER GRPHICSCOURSE CODE: 16MMU503BUNIT: VBATCH: 2016-2019

a view plane taken as the  $x_v, y_v$ , plane. Surface 5, is closest at this position, so its surface intensity value at (x, y) is saved.

We can implement the depth-buffer algorithm in normalized coordinates, so that z values range from 0 at the back clipping plane  $Z_{max}$  at the front clip ping plane. The value of  $Z_{max}$ , can be set either to 1 (for a unit cube) or to the largest value that can be stored on the system.

As implied by the name of this method, two buffer areas are required. A depth buffer is used to store depth values for each (x, y) position as surfaces are processed, and the refresh buffer stores the intensity values for each position. Initially,

all positions in the depth buffer are set to 0 (minimum depth), and the refresh buffer is initialized to the background intensity. Each surface listed in the polygon tables is then processed, one scan line at a time, calculating the depth (z value) at each (x, y) pixel position. The calculated depth is compared to the value

Previously stored in the depth buffer at that position. If the calculated depth is p a t e r than the value stored in the depth buffer, the new depth value is stored, and the surface intensity at that position is determined and in the same xy location in the refresh buffer.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE Page 6/15

# COURSE NAME: COMPUTER GRPHICS UNIT: V BATCH: 2016-2019

At view-plane position (x, y), surface S, has the smallest depth from the view plane and so is visible at that position.

We summarize the steps of a depth-buffer algorithm as follows:

1. Initialize the depth buffer and refresh buffer so that for all buffer positions (x, y),

depth(x, y) = 0,  $refresh(x, y) = l_{backgnd}$ 

2. For each position on each polygon surface, compare depth values to previously stored values in the depth buffer to determine visibility.

- Calculate the depth *t* for each (*x*, *y*) position on the polygon.
- If z > depth(x, y), then set

depth(x, y) = z,  $refresh(x, y) = I_{surf}(x, y)$ 

Where  $l_{background}$  is the value for the background intensity, and  $l_{surf(x,y)}$  is the projected intensity value for the surface at pixel position (x, y). After all surfaces have been processed, the depth buffer contains depth values for the visible surfaces and the buffer contains the corresponding intensity values for those surfaces.

Depth values for a surface position (x, y) are calculated from the plane equation for each surface:

## COURSE NAME: COMPUTER GRPHICS UNIT: V BATCH: 2016-2019

From position (x, y) on a scan line, the next position across the line has coordinates (X + 1, y), and the position immediately below on the next line has coordinates (x, y - 1).

For any scan line adjacent horizontal positions across the line differ by 1, and a vertical y value on an adjacent scan line differs by 1. If the depth of position (x, y) has been determined to be z, then the depth z' of the next position (x + y)

1, y) along the scan line is obtained

The ratio -A/C is constant for each surface, so succeeding depth values across a scan line are obtained from preceding values with a single addition.

#### Area Sub division Method

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE Page 8/15

# CLASS: III B.SC MATHEMATICSCOURSE NAME: COMPUTER GRPHICSCOURSE CODE: 16MMU503BUNIT: VBATCH: 2016-2019

This technique for hidden-surface removal is essentially an image-space method, but object-space operations can be used to accomplish depth ordering of surfaces. The area-subdivision method takes advantage of area coherence in a scene by locating those view areas that represent part of a single surface. We apply this method by successively dividing the total viewing area into smaller and smaller rectangles until each small area is the projection of part of n single visible surface or no surface at all.

To implement this method, we need to establish tests that can quickly identify the area as part of a single surface or tell us that the area is too complex to analyze easily. Starting with the total view, we apply the tests to determine whether we should subdivide the total area into smaller rectangles. If the tests indicate that the view is sufficiently complex, we subdivide it. Next. we apply the tests to each of the smaller areas, subdividing these if the tests indicate that visibility of a single surface is still uncertain. We continue this process until the subdivisions are easily analyzed as belonging to a single surface or until they are reduced to the size of a single pixel. An easy way to do this is to successively divide the area into four equal parts at each step, as shown in Fig. 13-20. This approach is similar to that used in constructing a quad tree. A viewing area with a resolution of 1024 by 1024 could be subdivided ten times in this way before a sub area is reduced to a pint.

Tests to determine the visibility of a single surface within a specified area are made by comparing surfaces to the boundary of the area. There are four possible relationships that a surface can have with a specified area boundary. We can describe these relative surface characteristics in the following way

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE Page 9/15

# COURSE NAME: COMPUTER GRPHICS UNIT: V BATCH: 2016-2019

#### Dividing a square area into equal-sized quadrants at each

Step.

Surrounding surface-One that completely encloses the area. Overlapping surface-One that is partly inside and partly outside the area. Inside surface-One that is completely inside the area. Outside surface-One that is completely outside the area.

The tests for determining surface visibility within an area can be stated in terms of these four classifications. No further subdivisions of a specified area are needed if one of the following conditions is true:

- 1. All surfaces are outside surfaces with respect to the area.
- 2. Only one inside, overlapping, or surrounding surface is in the area.
- 3. A surrounding surface obscures all other surfaces within the area boundaries.

#### **COMPUTER ANIMATION**

Animation means giving life to any object in computer graphics. It has the power of injecting energy and emotions into the most seemingly inanimate objects. Computer-assisted animation and computer-generated animation are two categories of computer animation. It can be presented via film or video.

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE Page 10/15

# CLASS: III B.SC MATHEMATICSCOURSE NAME: COMPUTER GRPHICSCOURSE CODE: 16MMU503BUNIT: VBATCH: 2016-2019

The basic idea behind animation is to play back the recorded images at the rates fast enough to fool the human eye into interpreting them as continuous motion. Animation can make a series of dead images come alive. Animation can be used in many areas like entertainment, computer aided-design, scientific visualization, training, education, ecommerce, and computer art.

#### STEPS FOR DESIGNING ANIMATION SEQUENCES.

- 1. Storyboard Layout
- 2. Object definitions
- 3. Key frame specifications
- 4. Generation of in-between frames

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE Page 11/15

#### KARPAGAM ACADEMY OF HIGHER EDUCATION

CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B COURSE NAME: COMPUTER GRPHICS UNIT: V BATCH: 2016-2019

#### GENERAL COMPUTER ANIMATION FUNCTIONS

Animation software provide basic functions to create animation and process the individual object.

FUNCTIONS

Manipulate data object database.

here to draw the line but the action intende

nbetween is not just he

Motion generation.

Object rendering.

#### **Raster Animations**

Real-time animations can be generated using raster operations. n computer animation, the term "raster graphics" refers to animation frames made of pixels rather than scalable components, such as vertices, edges, nodes, paths or vectors. Storing images as pixels

Prepared by Dr.S.Uma maheswari, Department of Computer Applications, KAHE Page 12/15

# CLASS: III B.SC MATHEMATICSCOURSE NAME: COMPUTER GRPHICSCOURSE CODE: 16MMU503BUNIT: VBATCH: 2016-2019

rather than vectors or vertices enables much deeper and more realistic lighting and color because the computer doesn't have to render each frame in real time as it does in a 3-D video game. However, because a fast PC can take 10 to 20 minutes to render one frame, rendering an entire animation usually requires a network of render nodes.

### **COMPUTER ANIMATION LANGUAGES**

### General purpose languages:

• C,C++,Pascal, or Lisp(control animation sequences).

### Specialized animation languages

- Key frame systems
- Parameterized systems
- Scripting systems

### **KEYFRAME SYSTEMS**

A keyframe is a frame where we define changes in animation. Every frame is a keyframe when we create frame by frame animation. When someone creates a 3D animation on a computer, they usually don't specify the exact position of any given object on every single frame. They create keyframes.

Keyframes are important frames during which an object changes its size, direction, shape or other properties. The computer then figures out all the in-between

### CLASS: III B.SC MATHEMATICS COURSE CODE: 16MMU503B U

### COURSE NAME: COMPUTER GRPHICS UNIT: V BATCH: 2016-2019

frames and saves an extreme amount of time for the animator. The following illustrations depict the frames drawn by user and the frames generated by computer.

### **MOTION SPECIFICATION**

There are several ways in which the motions of objects can be specified in an animation system. We can define motion in very explicit tems, or We can use more abstract or more general approaches.

### **Direct Motion Specification:**

The most straightforward method for defining a motion sequence is direct specification of the motion paremeters. Here, We explicitly give the rotation angles and translation vectors. Then the geometric transformation matrices are applied to transform co-ordinate positions. Alternatively, We could use an approximating equation to specify certain kinds of motions. These methods can be used for simple user programmed animation sequences.

### **Goal Directed Systems:**

At the opposite extreme, We can specify the motions that are to take place in general terms that abstractly describe the actions. these systems are referred to as goal directed because they determine specific motion parameters given the goals of the animation. For example, We could specify that we want an object to "walk " or to "run" to a particular destination. Or We could state that we want an object to "pick up " some other specified object. The inpute directive are then interpreted in term of component motions that will accomplish the selected task. Human motion, for instance, can be defined as a heirarchical structure of sub motion for the toros, limbs,and so forth.

### **POSSIBLE QUESTIONS**

### UNIT V

### PART-A (20 Marks)

### (Q.No 1 to 20 Online Examination)

### PART-B (2 Marks)

- 1. What are the two approaches for visible surface detection method.
- 2. Write the advantages of sorting method
- 3. What are the uses for coherence method.
- 4. What is computer animation?
- 5. Name the specialized animation languages.
- 6. What is a keyframe?

### PART –C (6marks)

- 1. Discuss in detail about Depth buffer method with its steps
- 2. Discuss about Area subdivision method
- 3. Discuss in detail about visible surface detection method.
- 4. Write briefly on Visible surface detection algorithms
- 5. Discuss briefly on steps for designing animation sequences.
- 6. Write short notes on computer animation languages
- 7. Discuss briefly on several ways of motion specification.

#### B.Sc. DEGREE EXAMINATION, APRIL 2014 Sixth Semester

#### COMPUTER SCIENCE

#### COMPUTER GRAPHICS

Time: 3 hours

Maximum : 100 marks

#### PART – A (15 x 2 = 30 Marks) Answer ALL the Questions

1. List the various applications of Computer Graphics?

2. Define persistence.

3. Mention any two drawbacks of DVST.

4. Which Input device is directly used on monitor and how it has been done

5. Differentiate between Input and Output device with one example

6. Define plotter.

7. Mention the steps used in DDA line drawing algorithm.

8. Give the matrix representation of 2D transformation

9. Write the properties of Circles

10. How the window to view-port transformation is performed

11. Give a note on Point clipping

12. How the text are clipped in text clipping process

13. Write the transformation equations of 3D

14. List some Visible Surface Detection Algorithms

15. Give a brief note on depth buffer method.

#### PART B (5 X 14= 70 Marks) Answer ALL the Questions

#### 16. (a) Discuss about Color CRT Monitors.

#### Or

(b) Write the working principles of Refresh CRT and a detail Description of Each component in CRT.

17. (a) Give a short note of the following Input Devices

 Digitizers
 Data glove
 Track ball and Space ball

(b) Give a short note of the following Output Devices i. Printer ii. Plotter

 (a) Explain in detail of Bresenham's Line Drawing algorithm. Or

- (b) Describe about 2D Transformation and composite Transformation.
- 19. (a) How the polygon clipping process takes place in Sutherland-Hodgman polygon clipping algorithm.

(b) How the line clipping process happens in Cohen Sutherland Line Clipping Algorithm.

-----

 20. (a) Discuss about various 3D Geometric Transformation display methods. Or
 (b) Explain in Detail about Perspective Projection with neat diagram.

#### PART - A (15 x 2 = 30 Marks)Answer ALL the Questions

Define the computer graphics
 What is called flat panel display?
 What is the use of 3 Dimensional viewing devices?
 What is track ball?
 What is a joystick?
 Define Printer?
 What is print clipping?
 What is translation?
 Write about Scaling?
 What is called point?
 Define Polygon Clipping
 What is the purpose of viewing pipeline?
 Define parallel projection
 What is back face detection?
 Write about Depth Butter method?

#### PART B (5 X 14= 70 Marks) Answer ALL the Questions

16. a. Give a note on color CRT monitors. Or
b. Briefly explain about Three Dimensional viewing devices

- 17. a. Explain about Input Device. Or
  b. Explain the working principle of different types of printes.
- 18. a. Explain about the Viewing Pipeline concept.
   Or
   b. Write the algorithm of Sutherland Hodgeman Polygon clipping and explain it
- with an example. 19. a. Discuss about 3D Geometric transformations
- Or b. Explain about Depth Buffer method in details.
- 20. Compulsory : -

Compulsory- Give a note on composite transformation in details

### PART – A (20X ½ = 10 Marks) Answer ALL the Questions

1. The display is used in television sets a) DVST b) storage tube c) cathode ray tube d) laser scan

- 3. Circle exhibits \_\_\_\_\_ symmetry a) Bilateral b) four way c) eight way d) linear
- 4. In the equation of line y=mx+b, \_\_\_\_\_ is called the slope of the linea) x b) y c) m d) b
- 5. Which of these is not a basic type of transformation?a) translation vector b) translation matrix c) translation constants d) None
- 6. v = tx I + ty J is called the a) Two b) Three c) Single d) Multi
- 8. An Object in a plane is a set ofa) picture b) images c) lines d) points
- 9. \_\_\_\_\_ is a process of altering the dimension of an object a) scaling b) rotation c) clipping d) None

- 10. Which of these are basic types of projections?a) Parallel b) perspective c) both d) none
- algorithm does not suit for 3 dimensional clipping.
   a) Cohen Sutherland b) Bresenham c) Sutherland Hodgman d) None of the above
- If the direction of rotation is counterclockwise then angle is said to be

   a) positive b) negative c) equal to zero d) none
- 14. Applying Scaling to a point P(x,y) the new point P' has coordinate values\_\_\_\_\_\_a) x.sx,y.sy b) x+sx,y+sy c) x.1/sx,y.1/sx d) x-xs,y-sy
- 15. is the opposite operation performed by the transformationa) iterative b) integration c) differential d) simple
- 16. The digital differential analyzer generates lines from \_\_\_\_\_\_\_ equation a) Pixel element b) Picture element c) point element d) Pixel
- 17. In \_\_\_\_\_\_ coordinate system, the points are addressed by x and y coordinates a) Absolute b) relative c) Cartesian d) basic
- 18. What is dpi?a) Dots per inch b) Digits per inch c) Division per inch d) none
- 19. Which of the following are image file?a) .doc b) .xls c) .jpeg d) .http
- 20. \_\_\_\_\_ projection is called converging projectors.a) Parallel b) Perspective c) Isometric d) Axonometric

#### PART B (5 X 4= 20 Marks) Answer ALL the Questions

- 21. (a) Explain color CRT monitor with an example. (OR)
  - (b) Write short notes on video display devices.
- 22. (a) Differentiate track ball and space ball (OR)
  - (b) Describe the following: a) Image scanner b) Touch panel
- 23. (a) Explain the methods of line drawing algorithm. (OR)
  - (b) Derive decision parameter for the midpoint circle algorithm with the radius r=10

24. (a) Write short notes on point clipping operations.

(OR)

- (b) Explain the four possible cases when processing vertices in a polygon.
- 25. (a) Write the method to display an object in 3D that is in world co-ordinates. (OR)
  - (b) Write short notes on parallel projection.

### PART C (3 x 10 = 30 Marks) Answer any THREE Questions

26. Give a detailed account on flat panel displays.

27. Explain hard copy devices in detail.

28. Enumerate the mid point algorithm to generate a circle.

29. Explain in detail about Cohen-Sutherland line clipping algorithm.

30. Discuss in detail about 3D co-ordinate axis rotation.

Reg No. ..... [16MMU503B]

### Karpagam Academy of Higher Education (Established Under Section 3 of UGC Act 1956) COIMBATORE – 641 021 B.Sc Degree Examination (For the candidates admitted from 2016 onwards) Fifth Semester Second Internal Exam August 2018 COMPUTER GRAPHICS

Duration: 2 Hrs Date & Session: Maximum Marks: 50 Marks Class: III B. Sc Maths

#### Part - A (20 X 1 = 20 Marks) (Answer all the Questions)

| 1.  | Pixel positions along a line path are determined by sampling at unit              |  |  |  |  |  |
|-----|---|--|--|--|--|--|
|     | a) <b>x intervals</b> b)y intervals c)x and y d)x-y                               |  |  |  |  |  |
| 2.  | The performance of the DDA algorithm by separating the increments m and 1/m into  |  |  |  |  |  |
|     | parts   |  |  |  |  |  |
|     | a) <b>integer and fractional</b> b) scan line positions                           |  |  |  |  |  |
|     | c) Functional line d) slope of the curve = -1                                     |  |  |  |  |  |
| 3.  | 3. An implementation of bresenham line drawing for slope in the range             |  |  |  |  |  |
|     | given in the following procedure  |  |  |  |  |  |
|     | a)m>1 b) $0 < m < 1$ c)m<1 d) $0 > m > 1$   |  |  |  |  |  |
| 4.  | Bresenham's circle generating algorithm will take reflections of                  |  |  |  |  |  |
|     | a) Two octets b) <b>One octet</b> c) Three octets d)Four octets                   |  |  |  |  |  |
| 5.1 | Eight-way symmetry is used by reflecting each calculated point around each axis   |  |  |  |  |  |
|     | a) $35^{\circ}$ b) $180^{\circ}$ c) $45^{\circ}$ d) $90^{\circ}$                  |  |  |  |  |  |
| 6.  | is accomplished by calculating intermediate positions along the line path between |  |  |  |  |  |
| t   | wo specified endpoint positions.  |  |  |  |  |  |
| _   | a) DDA b) Parellel Lines c) Line drawing d) Bresenham's                           |  |  |  |  |  |

- - a) Concatenation matrices b) Composition matrices
  - c) **both a & b** d) deformation matrices
- 16. Character sizes approximately ranges to a)1/12 inch b)<sup>3</sup>/<sub>4</sub> inch c)2/5 inch d)<sup>1</sup>/<sub>2</sub> inch
- 17. \_\_\_\_\_ is a Rigid-body transformation\_that moves object without deformation a)**Translation** b)Rotation c)Scaling d)Moving
- 18. This transformation alters the size of an object.a)Translation b)Rotation c)Scaling d)Shrinking
- 19. \_\_\_\_\_ means calculating the matrix product of the individual transformations
   a)Basic transformations b)Composite Transformations
   c)Multiple transformations d) Compound Transformations
- 20. In Scaling Transformation if the value of sx & sy is 1, it leaves the size of objects
  a) unchanged b)enlarged c)reduced d)uniform scaled

### Part - B (3 X 2=6 Marks) (Answer all the Questions)

- 21. What is set Pixel() and getPixel()? Ans: To load an intensity value into the frame buffer at a position to column x and line
- y, the procedure used is

Setpixel (x, y, intensity)

To retrieve the current frame buffer intensity by calling the procedure

Getpixel(x, y)

22. Define Translation.

Ans: Translation is a Rigid-body transformation\_that moves object without deformation.

23. Write the transformation equation for Scaling. Ans: Transformation equation in the matrix form :

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} sx & 0 \\ 0 & sy \end{bmatrix} \cdot \begin{bmatrix} x \\ y \end{bmatrix}$$
  
**p' =s.p**

Any positive values can be assigned to the scaling factors sx & sy.

### Part - C (3 X 8 =24 Marks) (Answer all the Questions)

24. (a)Explain DDA Line Algorithm DDA algorithm is a faster method for calculating pixel positions.. The Cartesian slope

intercept equation for a straight line is

$$y=m.x+b \rightarrow (1)$$

Here m represents slope of the line and b represents y intercept. Let us consider two end points are (x1, y1) & (x2, y2).

Calculating slope and intercept values

$$m = y^2 - y_1 / x^2 - x_1 \rightarrow (2)$$
$$b = y_1 - m \cdot x_1 \rightarrow (3)$$
$$\Delta y = m \cdot \Delta x \rightarrow (4)$$

 $\Delta x = \Delta y/m \rightarrow (5)$ 

Slope magnitudes can set deflection of the voltage.

If it is a positive slope

(1) The slope is less than or equal to 1 compute each successive y as

 $\mathbf{Y}_{k+1} = \mathbf{Y}_k + \mathbf{m}$ 

Subscript k takes integer value starting from 1 and increase by 1 until the final end point is reached.

(2) the slope is greater than 1 then calculate each succeeding x value as

 $X_{k+1} = X_k + (1/m)$ 

If the process is from right point to left (ie reverse)

$$Y_{k+1} = Y_k - m$$
  
 $X_{k+1} = X_k - (1/m)$ 

(b) Explain Bresenhams Line Drawing Algorithm

Ans: Bresenham's Line - Drawing Algorithm

- Input the two line endpoints and store the left endpoint in (x<sub>0</sub>, y<sub>0</sub>).
- Load (x<sub>0</sub>,y<sub>0</sub>) into the frame buffer; that is plot the first point.
- Calculate constants  $\Delta x$ ,  $\Delta y$ ,  $2\Delta y$ , and  $2\Delta y 2\Delta x$ , and obtain the starting value for the decision parameter as

$$p_0 = 2\Delta y - \Delta x$$

- At each  $x_k$  along the line, starting at k = 0, perform the following test:
- If  $p_k < 0$ , the next point to plot is  $(x_k + 1, y_k)$  and

$$p_k + 1 = p_k + 2\Delta y$$

Otherwise, the next point to plot is  $(x_k + 1, y_k + 1)$  and

$$p_k + 1 = p_k + 2\Delta y - 2\Delta x$$

- Repeat step 4  $\Delta x$  times.
- 25. (a) Explain Midpoint circle algorithm.

#### Midpoint Circle Algorithm

• Input radius r and circle center (x<sub>c</sub>,y<sub>c</sub>), and obtain the first point on the circumference of a circle centered on the origin as

 $(x_0, y_0) = (0, r)$ 

• Calculate the initial value of the decision parameter as

$$p_0 = 5/4 - r$$

At each x<sub>k</sub>, position, starting at k = 0, perform the following test : If p<sub>k</sub> < 0, the next point along the circle centered on (0,0) is (x<sub>k+1</sub>, y<sub>k</sub>) and

$$p_{k+1} = p_k + 2x_{k+1} + 1$$

Otherwise, the next point along the circle is (xk + 1, yk - 1) and

$$p_{k+1} = p_k + 2x_{k+1} + 1 - 2y_{k+1}$$

Where  $2x_{k+1} = 2x_k + 2$  and  $2y_{k+1} = 2y_k - 2$ .

- Determine symmetry points in the other seven octants.
- Move each calculated pixel position (x,y) onto the circular path centered on (x<sub>c</sub>, y<sub>c</sub>) and plot the coordinate values:

$$x=x+x_{c}$$
 ,  $y\!\!=y+y_{c}$ 

• Repeat steps 3 through 5 until x >= y;

#### (**OR**)

- (b) Discuss on Conic sections. **The General Equation for a Conic Section:**   $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$  **The type of section can be found from the sign of:** B<sup>2</sup> - 4AC If B<sup>2</sup> - 4AC is
  - a. < 0ellipse, circle, point or no curve.
  - b. = 0parabola, 2 parallel lines, 1 line or no curve.
  - > Ohyperbola or 2 intersecting lines.
- 26. (a) Explain Basic transformations in detail. BASIC TRANSFORMATION:
  - 1. TRANSLATION.
  - 2. ROTATION.
  - 3. SCALING.

### 1. TRANSLATION: -

- It is applied to an object by repositioning it along a straight line from one coordinate location to another.
- Translation equations as a single matrix equations by column vectors represent the coordinates:

P' = P +T. → (1)

Where **P**= 
$$\begin{bmatrix} x1\\ x2 \end{bmatrix}$$
, **P**' =  $\begin{bmatrix} x1'\\ x2' \end{bmatrix}$ , **T** =  $\begin{bmatrix} tx\\ ty \end{bmatrix}$ 

• In terms of coordinate row vectors :

$$\mathbf{P} = \begin{bmatrix} x, y \end{bmatrix} \& \mathbf{T} = \begin{bmatrix} tx, ty \end{bmatrix}$$

### 2. <u>ROTATION:</u>

- A 2-D rotation is applied to an object by repositioning it along a circular path in the XY plane.
- The transformation equations for the rotated coordinates are obtained by the trigonometric relationship.

$$X' = xr + (x - xr) \cos\Theta - (y - yr) \sin\Theta$$
$$Y' = yr + (x - xr) \sin\Theta + (y - yr) \cos\Theta$$

Every point on an object is rotated through the same angle

### 3. SCALING:

- Scaling transformation alters the size of an object.
- For polygon the scaling can be carried out by multiplying the coordinate values (x , y) of each vertex by scaling factors sx & sy to produce the transformed coordinates (x', y') :

$$x' = x.sx \& y' = y.sy \rightarrow (1)$$

- Scaling factors sx scales object in the x-direction & sy in the y-direction.
- Transformation equation in the matrix form :

$$\begin{bmatrix} x'\\ y' \end{bmatrix}_{=} \begin{bmatrix} sx & 0\\ 0 & sy \end{bmatrix} \cdot \begin{bmatrix} x\\ y \end{bmatrix}$$
  
**p' =s.p**

#### (OR) <u>b)General Pivot-Point Rotation:</u>

- Rotation about any selected pivot-point (x, y) by performing translation-rotation-translation.
- <u>Steps:</u>
  - a) Translate the object so that the pivot point position is moved to the coordinate origin.
  - b) Rotate the object about the coordinate origin.
  - c) Translate the object so that the pivot point is returned to its original position.

### 2. <u>General Fixed Point Scaling:</u>

- a) Translate objects so that the fixed point coincides with the coordinate origin.
- b) Scale the object with respect to the coordinate origin.

Use the inverse translation of step1 to return to the original position

#### Karpagam Academy of Higher Education (Established Under Section 3 of UGC Act 1956) COIMBATORE – 641 021 B.Sc Degree Examination (For the candidates admitted from 2016 onwards) Fifth Semester Third Internal Exam October 2018 COMPUTER GRAPHICS

Duration: 2 Hrs Date & Session:

#### Maximum Marks: 50 Marks Class: III B. Sc Maths

#### Part - A (20 X 1 = 20 Marks) (Answer all the Questions)

| 1 is defined as a mapping of a point P to its image P' in the view plane.       |  |                             |                        |  |  |  |

#### Part - B (3 X 2=6 Marks) (Answer all the Questions)

- 21. State the different clipping operations available
- Point Clipping
- Line Clipping (straight-line segments)
- Area Clipping (polygons)
- Curve Clipping
- Text Clipping

#### 22. Define perspective projection

In perspective projection, the distance from the center of projection to project plane is finite and the size of the object varies inversely with distance which looks more realistic. The distance and angles are not preserved and parallel lines do not remain parallel. Instead, they all converge at a single point called **center of projection** or **projection reference point** 

#### 23. What is a keyframe?

A **keyframe** is a frame where we define changes in **animation. Keyframes**are important frames during which an object changes its size, direction, shape or other properties.

### Part - C (3 X 8 =24 Marks) (Answer all the Questions)

- 24. a) What is Window and View port Coordinate system and how the transformations are performed
  - 1. Window-to-Viewport transformation is the process of transforming a two-dimensional, world-coordinate scene to device coordinates.

- 2. In particular, objects inside the world or clipping window are mapped to the viewport. The viewport is displayed in the interface window on the screen.
- 3. In other words, the clipping window is used to select the part of the scene that is to be displayed. The viewport then positions the scene on the output device.

- 1. This transformation involves developing formulas that start with a point in the world window, say (xw, yw).
- 2. The formula is used to produce a corresponding point in viewport coordinates, say (xv, yv). We would like for this mapping to be "proportional" in the sense that if xw is 30% of the way from the left edge of the world window, then xv is 30% of the way from the left edge of the viewport.
- 3. Similarly, if yw is 30% of the way from the bottom edge of the world window, then yv is 30% of the way from the bottom edge of the viewport. The picture below shows this proportionality.

- 1. The position of the viewport can be changed allowing objects to be viewed at different positions on the Interface Window.
- 2. Multiple viewports can also be used to display different sections of a scene at different screen positions. Also, by changing the dimensions of the viewport, the size and proportions of the objects being displayed can be manipulated.
- 3. Thus, a zooming affect can be achieved by successively mapping different dimensioned clipping windows on a fixed sized viewport.

4. If the aspect ratio of the world window and the viewport are different, then the image may look distorted.

(b)Explain briefly on Text clipping.

Various techniques are used to provide text clipping in a computer graphics. It depends on the methods used to generate characters and the requirements of a particular application. There are three methods for text clipping which are listed below -

- All or none string clipping
- All or none character clipping
- Text clipping

The following figure shows all or none string clipping -

# After Clipping

In all or none string clipping method, either we keep the entire string or we reject entire string based on the clipping window. As shown in the above figure, STRING2 is entirely inside the clipping window so we keep it and STRING1 being only partially inside the window, we reject.

The following figure shows all or none character clipping -

Before Clipping

After Clipping

This clipping method is based on characters rather than entire string. In this method if the string is entirely inside the clipping window, then we keep it. If it is partially outside the window, then -

- You reject only the portion of the string being outside
- If the character is on the boundary of the clipping window, then we discard that entire character and keep the rest string.

The following figure shows text clipping -

# Before Clipping

# After Clipping

This clipping method is based on characters rather than the entire string. In this method if the string is entirely inside the clipping window, then we keep it. If it is partially outside the window, then

- You reject only the portion of string being outside.
- If the character is on the boundary of the clipping window, then we discard only that portion of character that is outside of the clipping window.

25. (a) Explain working methodology of Three Dimensional Display Methods.

Parallel Projection Perspective Projection Surface Rendering Stereoscopic views

(OR)

(b) Explain the concept of parallel projections with an Example.

Parallel projection discards z-coordinate and parallel lines from each vertex on the object are extended until they intersect the view plane. In parallel projection, we specify a direction of projection instead of center of projection.

In parallel projection, the distance from the center of projection to project plane is infinite. In this type of projection, we connect the projected vertices by line segments which correspond to connections on the original object.

Parallel projections are less realistic, but they are good for exact measurements. In this type of projections, parallel lines remain parallel and angles are not preserved. Various types of parallel projections are shown in the following hierarchy.

### **26.** (a) Write briefly on General Computer Animation functions

Animators have invented and used a variety of different animation techniques. Basically there are six animation technique which we would discuss one by one in this section.

Traditional Animation (frame by frame)

Traditionally most of the animation was done by hand. All the frames in an animation had to be drawn by hand. Since each second of animation requires 24 frames (film), the amount of efforts required to create even the shortest of movies can be tremendous.

### Keyframing

In this technique, a storyboard is laid out and then the artists draw the major frames of the animation. Major frames are the ones in which prominent changes take place. They are the key points of animation. Keyframing requires that the animator specifies critical or key positions for the objects. The computer then automatically fills in the missing frames by smoothly interpolating between those positions.

#### Procedural

In a procedural animation, the objects are animated by a procedure -a set of rules - not by keyframing. The animator specifies rules and initial conditions and runs simulation. Rules are often based on physical rules of the real world expressed by mathematical equations.

#### Behavioral

In behavioral animation, an autonomous character determines its own actions, at least to a certain extent. This gives the character some ability to improvise, and frees the animator from the need to specify each detail of every character's motion.

(OR) (b)Discuss in detail on Keyframe systems

#### **KEYFRAME SYSTEMS**

A keyframe is a frame where we define changes in animation. Every frame is a keyframe when we create frame by frame animation. When someone creates a 3D animation on a computer, they usually don't specify the exact position of any given object on every single frame. They create keyframes.

Keyframes are important frames during which an object changes its size, direction, shape or other properties. The computer then figures out all the in-between frames and saves an extreme amount of time for the animator. The following illustrations depict the frames drawn by user and the frames generated by computer.

#### **MOTION SPECIFICATION**

There are several ways in which the motions of objects can be specified in an animation system. We can define motion in very explicit tems, or We can use more abstract or more general approaches.

#### **Direct Motion Specification:**

The most straightforward method for defining a motion sequence is direct specification of the motion paremeters. Here, We explicitly give the rotation angles and translation vectors. Then the geometric transformation matrices are applied to transform co-ordinate positions. Alternatively, We could use an approximating equation to specify certain kinds of motions. These methods can be used for simple user programmed animation sequences.

#### **Goal Directed Systems:**

At the opposite extreme, We can specify the motions that are to take place in general terms that abstractly describe the actions. these systems are referred to as goal directed because they determine specific motion parameters given the goals of the animation. For example, We could specify that we want an object to "walk " or to "run" to a particular destination. Or We could state that we want an object to "pick up " some other specified object. The inpute directive are then interpreted in term of component motions that will accomplish the selected task. Human motion, for instance, can be defined as a heirarchical structure of sub motion for the toros, limbs, and so forth.

#### **COMPUTER GRAPHICS**

Duration: 2 Hrs Date & Session:

#### Maximum Marks: 50 Marks Class: III B. Sc Maths

#### **Part - A (20 X 1 = 20 Marks)**

(Answer all the Ouestions) 1. . The \_\_\_\_\_\_ display is used in television sets a) DVST b)storage tube c)cathode ray tube d)laserscan 2. The ratio of image's width to its height, measured in unit length or no of pixels is called\_\_\_\_\_ a) Resolution b)raster c)size d)aspect ratio 3. The smallest picture unit accepted by display is termed as a \_\_\_\_\_ a) Dot b) **pixel** c)bit d)point 4. A \_\_\_\_\_\_\_ is a set of subroutines that provide high level access to graphics. a) Application b)graphics package c) hardware d)subprogram 5. Drawings, and color photos or text can be stored for computer processing with an \_\_\_\_\_ a) keyboard b)**Image Scanners** c) joystick d)mouse 6. A \_\_\_\_\_\_ is a ball that can be rotated with the fingers or palm of the hand a)**Trackball** b)Joystick c)mouse d)data glove 7. A\_\_\_\_\_ provides six degrees of freedom a) Trackball b)Joystick c)space ball d)data glove 8. The device which is designed to minimize the background sound is **Microphone** b)Digitizers c)Data glove d)Joy stick a) 9. To maintain a constant density in a line, dots are \_\_\_\_\_\_ spaced a) **Equally** b) less c) more d) not equally 10. A letter or a digits is formed by \_\_\_\_\_ of pixels. a) linear b)group c)multiple d)matrix 11. The ratio of image's width to its height is called \_\_\_\_\_ a) height b)**aspect ratio** c)image ration d)viewport 12. The \_\_\_\_\_\_ convert computer's electrical signals into visible images at high speed a)DVST b)laser scan c)CRT d)plasma panel 13. Which of the following is image file format? a).doc b).xls c)http d).jpeg 14. The \_\_\_\_\_ input can be used to initiate graphics operations or to enter data a)Voice systems b)Joystick c)space ball d)data glove 15. The term used to define all input and output devices in a computer system is \_\_\_\_\_\_ a)Monitor b)Software c)Shared d)hardware

16. A mouse ,touch screen, and a trackball are all examples of \_

a)Scanning Device b)Voice-Input Devices c)Pointing Device d)Output Device 17. The most popular input device for computer games is called \_\_\_\_\_.

a)Trackball b)Touch Screen c)Joystick d)Pointing stick 18.Pixel is

a) A memory b)An input c)A data structure d)Smallest addressable point
19. 24 bit representation provides a wide range of colors (16.7 million colours)
a) Lookup table b)RGB color space c)direct coding d)CMY color cube

20. \_\_\_\_\_ protocol is used to return the colour or index value of a pixel.

a) getValue() b)getIndex() c)getColor() d)getPixel()

#### Part - B (3 X 2=6 Marks) (Answer all the Questions)

21. Define resolution.

Ans: **Resolution** is the number of pixels (individual points of color) contained on a display monitor, expressed in terms of the number of pixels on the horizontal axis and the number on the vertical axis

- 22. Mention any four input devices.
  - Ans: Keyboard
  - Mouse
  - Joy Stick
  - Light pen
  - Track Ball
  - Scanner
  - Graphic Tablet
  - Microphone
  - Magnetic Ink Card Reader(MICR)
  - Optical Character Reader(OCR)
  - Bar Code Reader
  - Optical Mark Reader(OMR)
- 23. What do you mean by pel?

Ans: A pixel, **pel**, dots, or picture element is a physical point in a raster image, or the smallest addressable element in an all points addressable display device

### Part - C (3 X 8 =24 Marks) (Answer all the Questions)

24. (a) Explain the working of Refresh Cathode Ray Tubes with a neat diagram. Ans: The basic operation of a CRT.

- A beam of electrons (cathode rays) emitted by an electron gun, passes through focusing and deflection systems that direct the beam toward specified positions on the phosphor coated screen.
- The phosphor then emits a small spot of light at each position contacted by the electron beam. Because the light emitted by the phosphor fades very rapidly, some method is needed for maintaining the screen picture
- The primary components of an electron gun in a CRT are the heated metal cathode and a control grid
- The accelerating voltage can be generated with a positively charged metal coating on the

inside of the CRT envelope near the phosphor screen, or an accelerating anode can be used.

### (**OR**)

(b) Explain about the operation of an electron gun with a neat diagram?

- The electron gun is built to contain the accelerating anode and focusing system within the same unit.
- Intensity of the electron beam is controlled by setting voltage levels on the control grid, which is a metal cylinder that fits over the cathode.
- A high negative voltage applied to the control grid will shut off the beam by repelling electrons and stopping them from passing through the small hole at the end of the control grid structure.
- A smaller negative voltage on the control grid simply decreases the number of electrons passing through
- The focusing system in a CRT is needed to force the electron beam to converge into a small spot as it strikes the phosphor. Otherwise, the electrons would repel each other, and the beam would spread out as it approaches the screen
- 25. (a) Explain about Raster Scan Display.
  - Ans:
    - The most Common type of graphics monitor employing a CRT is the Raster -Scan
    - Display Based on Television Technology.
    - TV technology Electron beam swept acrosscreen one row at a time from top to bottom
    - Each row is referred to as a scan line

- This memory area holds the set of intensity values for all the screen points. Stored intensity values are then retrieved from the refresh buffer and painted on the screen one row. At a time.
- Picture information stored in refresh (frame) **buffer**
- Picture elements: screen point referred as "Pixel"
- Intensity Range of pixel positions depends on the capability of the raster system. In a simple black-and-white system each screen point is either on or off.
- So only one bit per pixel is needed to control the intensity of the screen positions.
- Bit value 1 indicates that the electron beam is to be turned on at that position.
- Bit value 0 indicates that the electron beam is to be turned of.
- Additional bits are needed when color and intensity variations can be displayed.

#### (**OR**)

(b) Explain about Random Scan Display

- CRT has the electron beam directed only to the pats of the screen where a picture is to be drawn .Random scan monitors draw a picture one line at a time also called vector, stroke or line drawing graphics.
- Random scan system depends on the number of lines to be displayed. Picture definition is stored as a set of line drawing commands in an area of memory referred to as the refresh display file
- Some time the refresh display file is called display list.
- To display a specified picture the system cycles through the set of commands in the file drawing each component line in turn. After all line drawing commands have been processed the system cycles back to the first line command in the list. Random scan displays are designed to all draw component lines of picture 30 to 60 times each second.
- Random scan system are designed for line drawing applications and cannot display realistic shaded scenes.

### 26. (a) Explain about Input devices.

#### **KEYBOARD:-**

• An alphanumeric keyboard on a graphics system is used primarily as a device for entering text strings.

### • MOUSE:

• A mouse is small hand-held box used to position the screen cursor. Wheels or rollers on the bottom of the mouse can be used to record the amount and direction of movement

#### • TRACKBALL AND SPACE BALL

• Trackball is a ball that can be rotated with the fingers or palm of the hand, to produce screen-cursor movement.

#### • SPACE BALL

 space ball provides six degrees of freedom. Unlike the trackball, a space ball does not actually move. Strain gauges measure the amount of pressure applied to the space ball to provide input for spatial positioning and orientation as the ball is pushed or pulled in various directions

#### • JOYSTICKS

• A joystick consists of a small, vertical lever (called the stick) mounted on a base that is used to steer the screen cursor around

#### • DATA GLOVE:-

• Data glove that can be used to grasp a "virtual" object. The glove is constructed with a series of sensors that detect hand and finger motions.

#### • DIGITIZERS:

 A common device for drawing, painting, or interactively selecting coordinate positions on an object is a digitizer. These devices can be used to input coordinate values in either a two-dimensional or a three-dimensional space

#### (**OR**)

(b) Explain about Hard copy devices.

#### **PRINTERS:**

- Printers are the most commonly used output device. They are used to print output on the paper. The output may be in the form of characters, symbols and graphics information printed on paper is called hardcopy
- The various types of printers in used today are:
  - Dot-Matrix Printers
  - Inkjet Printers
  - Drum Printers
  - Laser Printers.
- Printers produce output by either
- **Impact Printer** The types of printers that produce output on paper by striking the print hammer or wheel against an inked ribbon are called impact printers
- **Non impact Printer-** The printers that produce output on paper without striking the paper are known as non-impact printers.
