17MMU601A	RING THEORY AND LINEAR ALGEBRA II	6 2 0 6

Scope: On successful completion of course the learners gain about the behavior of polynomials and operators.

Objectives: To enable the students to learn and gain knowledge about polynomial rings over commutative rings, dual spaces, dual basis, double dual, minimal solutions to systems of linear equations, normal and self-adjoint operators.

UNIT I

RINGS

Polynomial rings over commutative rings - Division algorithm and consequences - Principal idealdomains - Factorization of polynomials - Reducibility tests - Irreducibility tests - Eisenstein criterion - Unique factorization in Z[x].

UNIT II

INTEGRAL DOMAINS

Divisibility in integral domains- Irreducibles – Primes - Unique factorization domains - Euclidean domains.

UNIT III VECTOR SPAC

VECTOR SPACES

Dual spaces - Dual basis - Double dual - Transpose of a linear transformation and its matrix in thedual basis - Annihilators - Eigen spaces of a linear operator - Diagonalizability - Invariant subspaces and Cayley-Hamilton theorem - The minimal polynomial for a linear operator.

UNIT IV

INNER PRODUCT SPACES

Inner product spaces and norms - Gram-Schmidt orthogonalisation process - Orthogonal complements - Bessel's inequality - The adjoint of a linear operator.

UNIT V

OPERATORS

Least Squares Approximation - Minimal solutions to systems of linear equations - Normal and self - Adjoint operators - Orthogonal projections and Spectral theorem.

SYLLABUS

Polynomial rings over commutative rings, division algorithm and consequences, principal idealdomains, factorization of polynomials, reducibility tests, irreducibility tests, Eisenstein criterion, unique factorization in Z[x].

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

RINGS OF POLYNOMIALS

Let R be a ring. A polynomial f(x) with coefficients in R is an infinite formal sum

$$\sum_{i=0}^{\infty} a_i x^i = a_0 + a_1 x + \dots + a_n x^n + \dots,$$

where $a_i \in R$ and $a_i = 0$ for all but a finite number of values of i. The a_i are coefficients of f(x). If for some $i \ge 0$ it is true that $a_i \ne 0$, the largest such value of i is the degree of f(x). If all $a_i = 0$, then the degree of f(x) is undefined.[†]

To simplify working with polynomials, let us agree that if $f(x) = a_0 + a_1x + \cdots + a_nx^n + \cdots$ has $a_i = 0$ for i > n, then we may denote f(x) by $a_0 + a_1x + \cdots + a_nx^n$. Also, if R has unity $1 \neq 0$, we will write a term $1x^k$ in such a sum as x^k . For example, in $\mathbb{Z}[x]$, we will write the polynomial 2 + 1x as 2 + x. Finally, we shall agree that we may omit altogether from the formal sum any term $0x^i$, or a_0 if $a_0 = 0$ but not all $a_i = 0$. Thus 0, 2, x, and $2 + x^2$ are polynomials with coefficients in \mathbb{Z} . An element of R is a **constant polynomial**.

Addition and multiplication of polynomials with coefficients in a ring R are defined in a way familiar to us. If

$$f(x) = a_0 + a_1 x + \dots + a_n x^n + \dots$$

and

$$g(x) = b_0 + b_1 x + \dots + b_n x^n + \dots,$$

then for polynomial addition, we have

 $f(x) + g(x) = c_0 + c_1 x + \dots + c_n x^n + \dots$ where $c_n = a_n + b_n$,

- **Theorem** The set R[x] of all polynomials in an indeterminate x with coefficients in a ring R is a ring under polynomial addition and multiplication. If R is commutative, then so is R[x], and if R has unity $1 \neq 0$, then 1 is also unity for R[x].
 - **Proof** That $\langle R[x], + \rangle$ is an abelian group is apparent. The associative law for multiplication and the distributive laws are straightforward, but slightly cumbersome, computations. We illustrate by proving the associative law.

Applying ring axioms to $a_i, b_j, c_k \in R$, we obtain

CLASS: II B.Sc MATHEMATICS COURSE CODE: 16MMU403

COURSE NAME: Ring Thory and Linear Algebra-II UNIT: I BATCH-2016-2019

$$\begin{split} \left[\left(\sum_{i=0}^{\infty} a_i x^i\right) \left(\sum_{j=0}^{\infty} b_j x^j\right) \right] \left(\sum_{k=0}^{\infty} c_k x^k\right) &= \left[\sum_{n=0}^{\infty} \left(\sum_{i=0}^n a_i b_{n-i}\right) x^n\right] \left(\sum_{k=0}^{\infty} c_k x^k\right) \\ &= \sum_{s=0}^{\infty} \left[\sum_{n=0}^s \left(\sum_{i+j+k=s}^n a_i b_j c_k\right) x^s\right] \\ &= \sum_{s=0}^{\infty} \left(\sum_{i+j+k=s}^s a_{s-m} \left(\sum_{j=0}^m b_j c_{m-j}\right)\right] x^s \\ &= \left(\sum_{i=0}^{\infty} a_i x^i\right) \left[\sum_{m=0}^{\infty} \left(\sum_{j=0}^m b_j c_{m-j}\right) x^m\right] \\ &= \left(\sum_{i=0}^{\infty} a_i x^i\right) \left[\left(\sum_{j=0}^{\infty} b_j x^j\right) \left(\sum_{k=0}^{\infty} c_k x^k\right)\right] \end{split}$$

The Evaluation Homomorphisms

Theorem (The Evaluation Homomorphisms for Field Theory) Let F be a subfield of a field E, let α be any element of E, and let x be an indeterminate. The map $\phi_{\alpha} : F[x] \rightarrow E$ defined by

$$\phi_{\alpha}(a_0 + a_1x + \dots + a_nx^n) = a_0 + a_1\alpha + \dots + a_n\alpha^n$$

for $(a_0 + a_1x + \cdots + a_nx^n) \in F[x]$ is a homomorphism of F[x] into *E*. Also, $\phi_{\alpha}(x) = \alpha$, and ϕ_{α} maps *F* isomorphically by the identity map; that is, $\phi_{\alpha}(a) = a$ for $a \in F$. The homomorphism ϕ_{α} is evaluation at α .

Proof The subfield and mapping diagram in Fig. 22.5 may help us to visualize this situation. The dashed lines indicate an element of the set. The theorem is really an immediate

KARPAGAM ACADEMY OF HIGHER EDUCATIONCLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

consequence of our definitions of addition and multiplication in F[x]. The map ϕ_{α} is well defined, that is, independent of our representation of $f(x) \in F[x]$ as a finite sum

 $a_0 + a_1 x + \dots + a_n x^n,$

since such a finite sum representing f(x) can be changed only by insertion or deletion of terms $0x^i$, which does not affect the value of $\phi_{\alpha}(f(x))$.

If $f(x) = a_0 + a_1x + \dots + a_nx^n$, $g(x) = b_0 + b_1x + \dots + b_mx^m$, and $h(x) = f(x) + g(x) = c_0 + c_1x + \dots + c_rx^r$, then

$$\phi_{\alpha}(f(x) + g(x)) = \phi_{\alpha}(h(x)) = c_0 + c_1\alpha + \dots + c_r\alpha',$$

while

$$\phi_{\alpha}(f(x)) + \phi_{\alpha}(g(x)) = (a_0 + a_1\alpha + \dots + a_n\alpha^n) + (b_0 + b_1\alpha + \dots + b_m\alpha^m)$$

Since by definition of polynomial addition we have $c_i = a_i + b_i$, we see that

$$\phi_{\alpha}(f(x) + g(x)) = \phi_{\alpha}(f(x)) + \phi_{\alpha}(g(x)).$$

Turning to multiplication, we see that if

$$f(x)g(x) = d_0 + d_1x + \dots + d_sx^s,$$

then

$$\phi_{\alpha}(f(x)g(x)) = d_0 + d_1\alpha + \dots + d_s\alpha^s,$$

while

$$\phi_{\alpha}(f(x))][\phi_{\alpha}(g(x))] = (a_0 + a_1\alpha + \dots + \alpha_n\alpha^n)(b_0 + b_1\alpha + \dots + b_m\alpha^m).$$

Since by definition of polynomial multiplication $d_j = \sum_{i=0}^{j} a_i b_{j-i}$, we see that

$$\phi_{\alpha}(f(x)g(x)) = [\phi_{\alpha}(f(x))][\phi_{\alpha}(g(x))].$$

Thus ϕ_{α} is a homomorphism.

The very definition of ϕ_{α} applied to a constant polynomial $a \in F[x]$, where $a \in F$. gives $\phi_{\alpha}(a) = a$, so ϕ_{α} maps F isomorphically by the identity map. Again by definition of ϕ_{α} , we have $\phi_{\alpha}(x) = \phi_{\alpha}(1x) = 1\alpha = \alpha$.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

Example Let F be Q and E be R in Theorem 22.4, and consider the evaluation homomorphism $\phi_0 : \mathbb{Q}[x] \to \mathbb{R}$. Here

$$\phi_0(a_0 + a_1x + \dots + a_nx^n) = a_0 + a_10 + \dots + a_n0^n = a_0.$$

Thus every polynomial is mapped onto its constant term.

Example Let F be \mathbb{Q} and E be \mathbb{R} in Theorem 22.4 and consider the evaluation homomorphism $\phi_2 : \mathbb{Q}[x] \to \mathbb{R}$. Here

$$\phi_2(a_0 + a_1x + \dots + a_nx^n) = a_0 + a_12 + \dots + a_n2^n.$$

Note that

$$\phi_2(x^2 + x - 6) = 2^2 + 2 - 6 = 0.$$

Thus $x^2 + x - 6$ is in the kernel N of ϕ_2 . Of course,

 $x^2 + x - 6 = (x - 2)(x + 3),$

and the reason that $\phi_2(x^2 + x - 6) = 0$ is that $\phi_2(x - 2) = 2 - 2 = 0$.

Example Let F be Q and E be C in Theorem 22.4 and consider the evaluation homomorphism $\phi_i : \mathbb{Q}[x] \to \mathbb{C}$. Here

$$\phi_i(a_0 + a_1x + \dots + a_nx^n) = a_0 + a_1i + \dots + a_ni^n$$

and $\phi_i(x) = i$. Note that

$$\phi_i(x^2 + 1) = i^2 + 1 = 0,$$

so $x^2 + 1$ is in the kernel N of ϕ_i .

Example Let F be Q and let E be R in Theorem 22.4 and consider the evaluation homomorphism $\phi_{\pi} : \mathbb{Q}[x] \to \mathbb{R}$. Here

$$\phi_{\pi}(a_0 + a_1x + \dots + a_nx^n) = a_0 + a_1\pi + \dots + a_n\pi^n.$$

It can be proved that $a_0 + a_1\pi + \cdots + a_n\pi^n = 0$ if and only if $a_i = 0$ for $i = 0, 1, \cdots, n$. Thus the kernel of ϕ_{π} is $\{0\}$, and ϕ_{π} is a one-to-one map. This shows that all *formal* polynomials in π with rational coefficients form a ring isomorphic to $\mathbb{Q}[x]$ in a natural way with $\phi_{\pi}(x) = \pi$.

Prepared by U.R.Ramakrishnan, Asst Prof, Department of Mathematics KAHE

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

Definition Let F be a subfield of a field E, and let α be an element of E. Let $f(x) = a_0 + a_1x + \dots + a_nx^n$ be in F[x], and let $\phi_{\alpha} : F[x] \to E$ be the evaluation homomorphism of Theorem 22.4. Let $f(\alpha)$ denote

$$\phi_{\alpha}(f(x)) = a_0 + a_1\alpha + \dots + a_n\alpha^n.$$

If $f(\alpha) = 0$, then α is a zero of f(x).

In terms of this definition, we can rephrase the classical problem of finding all real numbers r such that $r^2 + r - 6 = 0$ by letting $F = \mathbb{Q}$ and $E = \mathbb{R}$ and finding all $\alpha \in \mathbb{R}$ such that

$$\phi_{\alpha}(x^2 + x - 6) = 0.$$

that is, finding all zeros of $x^2 + x - 6$ in \mathbb{R} . Both problems have the same answer, since

$$\{\alpha \in \mathbb{R} \mid \phi_{\alpha}(x^2 + x - 6) = 0\} = \{r \in \mathbb{R} \mid r^2 + r - 6 = 0\} = \{2, -3\}.$$

- **Theorem** The polynomial $x^2 2$ has no zeros in the rational numbers. Thus $\sqrt{2}$ is not a rational number.
 - **Proof** Suppose that m/n for $m, n \in \mathbb{Z}$ is a rational number such that $(m/n)^2 = 2$. We assume that we have canceled any factors common to m and n, so that the fraction m/n is in lowest terms with gcd(m, n) = 1. Then

$$m^2 = 2n^2$$
.

where both m^2 and $2n^2$ are integers. Since m^2 and $2n^2$ are the same integer, and since 2 is a factor of $2n^2$, we see that 2 must be one of the factors of m^2 . But as a square. m^2 has as factors the factors of m repeated twice. Thus m^2 must have two factors 2. Then $2n^2$ must have two factors 2, so n^2 must have 2 as a factor, and consequently n has 2 as a factor. We have deduced from $m^2 = 2n^2$ that both m and n must be divisible by 2, contradicting the fact that the fraction m/n is in lowest terms. Thus we have $2 \neq (m/n)^2$ for any $m, n \in \mathbb{Z}$.

Thus the Pythagoreans ran right into the question of a solution of a polynomial equation, $x^2 - 2 = 0$. We refer the student to Shanks [36, Chapter 3], for a lively and totally delightful account of this Pythagorean dilemma and its significance in mathematics.

FACTORIZATION OF POLYNOMIALS OVER A FIELD

The Division Algorithm in F[x]

The following theorem is the basic tool for our work in this section. Note the similarity with the division algorithm for \mathbb{Z} given in Theorem 6.3, the importance of which has been amply demonstrated.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

Theorem (Division Algorithm for F[x]) Let

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_0$$

and

$$g(x) = b_m x^m + b_{m-1} x^{m-1} + \dots + b_0$$

be two elements of F[x], with a_n and b_m both nonzero elements of F and m > 0. Then there are unique polynomials q(x) and r(x) in F[x] such that f(x) = g(x)q(x) + r(x), where either r(x) = 0 or the degree of r(x) is less than the degree m of g(x).

Proof Consider the set $S = \{f(x) - g(x)s(x) | s(x) \in F[x]\}$. If $0 \in S$ then there exists an s(x) such that f(x) - g(x)s(x) = 0, so f(x) = g(x)s(x). Taking q(x) = s(x) and r(x) = 0, we are done. Otherwise, let r(x) be an element of minimal degree in S. Then

$$f(x) = g(x)q(x) + r(x)$$

for some $q(x) \in F[x]$. We must show that the degree of r(x) is less than m. Suppose that

$$r(x) = c_t x^t + c_{t-1} x^{t-1} + \dots + c_0,$$

with $c_j \in F$ and $c_t \neq 0$. If $t \ge m$, then

$$f(x) - q(x)g(x) - (c_t/b_m)x^{t-m}g(x) = r(x) - (c_t/b_m)x^{t-m}g(x),$$
(1)

and the latter is of the form

 $r(x) - (c_t x^t + \text{terms of lower degree}),$

which is a polynomial of degree lower than t, the degree of r(x). However, the polynomial in Eq. (1) can be written in the form

$$f(x) - g(x)[q(x) + (c_t/b_m)x^{t-m}],$$

so it is in S, contradicting the fact that r(x) was selected to have minimal degree in S.

Thus the degree of r(x) is less than the degree m of g(x).

For uniqueness, if

 $f(x) = g(x)q_1(x) + r_1(x)$

and

$$f(x) = g(x)q_2(x) + r_2(x),$$

then subtracting we have

$$g(x)[q_1(x) - q_2(x)] = r_2(x) - r_1(x).$$

Because either $r_2(x) - r_1(x) = 0$ or the degree of $r_2(x) - r_1(x)$ is less than the degree of g(x), this can hold only if $q_1(x) - q_2(x) = 0$ so $q_1(x) = q_2(x)$. Then we must have $r_2(x) - r_1(x) = 0$ so $r_1(x) = r_2(x)$.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

Example Let us work with polynomials in $\mathbb{Z}_5[x]$ and divide

$$f(x) = x^4 - 3x^3 + 2x^3 + 4x - 1$$

by $g(x) = x^2 - 2x + 3$ to find q(x) and r(x) of Theorem 23.1. The long division should be easy to follow, but remember that we are in $\mathbb{Z}_5[x]$, so, for example, 4x - (-3x) = 2x.

$$\begin{array}{r} x^2 - x - 3 \\ \hline x^2 - 2x + 3 \\ \hline x^4 - 3x^3 + 2x^2 + 4x - 1 \\ \hline x^4 - 2x^3 + 3x^2 \\ \hline -x^3 - x^2 + 4x \\ \hline -x^3 + 2x^2 - 3x \\ \hline -3x^2 + 2x - 1 \\ \hline -3x^2 + x - 4 \\ \hline x + 3 \end{array}$$

Thus

$$q(x) = x^2 - x - 3$$
, and $r(x) = x + 3$.

- **Corollary** (Factor Theorem) An element $a \in F$ is a zero of $f(x) \in F[x]$ if and only if x a is a factor of f(x) in F[x].
 - **Proof** Suppose that for $a \in F$ we have f(a) = 0. By Theorem 23.1, there exist q(x), $r(x) \in F[x]$ such that

$$f(x) = (x - a)q(x) + r(x),$$

where either r(x) = 0 or the degree of r(x) is less than 1. Thus we must have r(x) = c for $c \in F$, so

$$f(x) = (x - a)q(x) + c.$$

Applying our evaluation homomorphism, $\phi_a: F[x] \to F$ of Theorem 22.4, we find

$$0 = f(a) = 0q(a) + c,$$

so it must be that c = 0. Then f(x) = (x - a)q(x), so x - a is a factor of f(x).

Conversely, if x - a is a factor of f(x) in F[x], where $a \in F$, then applying our evaluation homomorphism ϕ_a to f(x) = (x - a)q(x), we have f(a) = 0q(a) = 0.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

Example Working again in $\mathbb{Z}_5[x]$, note that 1 is a zero of

$$(x^4 + 3x^3 + 2x + 4) \in \mathbb{Z}_5[x].$$

Thus by Corollary 23.3, we should be able to factor $x^4 + 3x^3 + 2x + 4$ into (x - 1)q(x) in $\mathbb{Z}_5[x]$. Let us find the factorization by long division.

$$\begin{array}{r} x^{3} + 4x^{2} + 4x + 1 \\ \underline{x - 1} \overline{\smash{\big)} x^{4} + 3x^{3} + 2x + 4} \\ \underline{x^{4} - x^{3}} \\ \underline{4x^{3}} \\ 4x^{3} \\ \underline{4x^{3} - 4x^{2}} \\ 4x^{2} + 2x \\ \underline{4x^{2} - 4x} \\ \underline{4x^{2} - 4x} \\ \underline{x - 1} \\ 0 \end{array}$$

Thus $x^4 + 3x^3 + 2x + 4 = (x - 1)(x^3 + 4x^2 + 4x + 1)$ in $\mathbb{Z}_5[x]$. Since 1 is seen to be a zero of $x^3 + 4x^2 + 4x + 1$ also, we can divide this polynomial by x - 1 and get

$$\begin{array}{r} x^{2} + 4 \\ x - 1 \overline{\smash{\big)}} x^{3} + 4x^{2} + 4x + 1 \\ \hline x^{3} - x^{2} \\ 0 + 4x + 1 \\ \underline{4x - 4} \\ 0 \end{array}$$

Since $x^2 + 4$ still has 1 as a zero, we can divide again by x - 1 and get

$$\begin{array}{r} x+1 \\ x-1 \overline{\smash{\big)} x^2 + 4} \\ \underline{x^2 - x} \\ x+4 \\ \underline{x-1} \\ 0 \end{array}$$

Thus $x^4 + 3x^3 + 2x + 4 = (x - 1)^3(x + 1)$ in $\mathbb{Z}_5[x]$.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

Corollary A nonzero polynomial $f(x) \in F[x]$ of degree *n* can have at most *n* zeros in a field *F*.

Proof The preceding corollary shows that if $a_1 \in F$ is a zero of f(x), then

$$f(x) = (x - a_1)q_1(x),$$

where, of course, the degree of $q_1(x)$ is n - 1. A zero $a_2 \in F$ of $q_1(x)$ then results in a factorization

$$f(x) = (x - a_1)(x - a_2)q_2(x).$$

Continuing this process, we arrive at

$$f(x) = (x - a_1) \cdots (x - a_r)q_r(x),$$

where $q_r(x)$ has no further zeros in F. Since the degree of f(x) is n, at most n factors $(x - a_i)$ can appear on the right-hand side of the preceding equation, so $r \le n$. Also, if $b \ne a_i$ for $i = 1, \dots, r$ and $b \in F$, then

$$f(b) = (b - a_1) \cdots (b - a_r)q_r(b) \neq 0$$
,

since F has no divisors of 0 and none of $b - a_i$ or $q_r(b)$ are 0 by construction. Hence the a_i for $i = 1, \dots, r \le n$ are all the zeros in F of f(x).

- Corollary If G is a finite subgroup of the multiplicative group (F*, ·) of a field F, then G is cyclic. In particular, the multiplicative group of all nonzero elements of a finite field is cyclic.
 - **Proof** By Theorem 11.12 as a finite abelian group, G is isomorphic to a direct product $\mathbb{Z}_{d_i} \times \mathbb{Z}_{d_2} \times \cdots \times \mathbb{Z}_{d_r}$, where each d_i is a power of a prime. Let us think of each of the \mathbb{Z}_{d_i} as a cyclic group of order d_i in *multiplicative* notation. Let m be the least common multiple of all the d_i for $i = 1, 2, \cdots, r$; note that $m \leq d_1 d_2 \cdots d_r$. If $a_i \in \mathbb{Z}_{d_i}$, then $a_i^{d_i} = 1$, so $a_i^m = 1$ since d_i divides m. Thus for all $\alpha \in G$, we have $\alpha^m = 1$, so every element of G is zero of $x^m 1$. But G has $d_1 d_2 \cdots d_r$ elements, while $x^m 1$ can have at most m zeros in the field F by Corollary 23.5, so $m \geq d_1 d_2 \cdots d_r$. Hence $m = d_1 d_2 \cdots d_r$, so the primes involved in the prime powers d_1, d_2, \cdots, d_r are distinct, and the group G is isomorphic to the cyclic group \mathbb{Z}_m .

Irreducible Polynomials

- **Definition** A nonconstant polynomial $f(x) \in F[x]$ is **irreducible over** F or is an **irreducible polynomial** in F[x] if f(x) cannot be expressed as a product g(x)h(x) of two polynomials g(x) and h(x) in F[x] both of lower degree than the degree of f(x). If $f(x) \in F[x]$ is a nonconstant polynomial that is not irreducible over F, then f(x) is **reducible** over F.
- **Example** Theorem 22.11 shows that $x^2 2$ viewed in $\mathbb{Q}[x]$ has no zeros in \mathbb{Q} . This shows that $x^2 2$ is irreducible over \mathbb{Q} , for a factorization $x^2 2 = (ax + b)(cx + d)$ for $a, b, c, d \in \mathbb{Q}$ would give rise to zeros of $x^2 2$ in \mathbb{Q} . However, $x^2 2$ viewed in $\mathbb{R}[x]$ is not irreducible over \mathbb{R} , because $x^2 2$ factors in $\mathbb{R}[x]$ into $(x \sqrt{2})(x + \sqrt{2})$.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

Example	Let us show that $f(x) = x^3 + 3x + 2$ viewed in $\mathbb{Z}_5[x]$ is irreducible over \mathbb{Z}_5 . If $x^3 + 3x + 2$
579997950 8 -1999	$3x + 2$ factored in $\mathbb{Z}_5[x]$ into polynomials of lower degree then there would exist at
	least one linear factor of $f(x)$ of the form $x - a$ for some $a \in \mathbb{Z}_5$. But then $f(a)$ would
	be 0, by Corollary 23.3. However, $f(0) = 2$, $f(1) = 1$, $f(-1) = -2$, $f(2) = 1$, and
	$f(-2) = -2$, showing that $f(x)$ has no zeros in \mathbb{Z}_5 . Thus $f(x)$ is irreducible over
	Z5. This test for irreducibility by finding zeros works nicely for quadratic and cubic
	polynomials over a finite field with a small number of elements.

Theorem Let $f(x) \in F[x]$, and let f(x) be of degree 2 or 3. Then f(x) is reducible over F if and only if it has a zero in F.

Proof If f(x) is reducible so that f(x) = g(x)h(x), where the degree of g(x) and the degree of h(x) are both less than the degree of f(x), then since f(x) is either quadratic or cubic, either g(x) or h(x) is of degree 1. If, say, g(x) is of degree 1, then except for a possible factor in F, g(x) is of the form x - a. Then g(a) = 0, which implies that f(a) = 0, so f(x) has a zero in F.

Conversely, Corollary 23.3 shows that if f(a) = 0 for $a \in F$, then x - a is a factor of f(x), so f(x) is reducible.

- **Theorem** If $f(x) \in \mathbb{Z}[x]$, then f(x) factors into a product of two polynomials of lower degrees r and s in $\mathbb{Q}[x]$ if and only if it has such a factorization with polynomials of the same degrees r and s in $\mathbb{Z}[x]$.
 - **Proof** The proof is omitted here.

Corollary If $f(x) = x^n + a_{n-1}x^{n-1} + \dots + a_0$ is in $\mathbb{Z}[x]$ with $a_0 \neq 0$, and if f(x) has a zero in \mathbb{Q} , then it has a zero m in \mathbb{Z} , and m must divide a_0 .

Proof If f(x) has a zero a in \mathbb{Q} , then f(x) has a linear factor x - a in $\mathbb{Q}[x]$ by Corollary 23.3. But then by Theorem 23.11, f(x) has a factorization with a linear factor in $\mathbb{Z}[x]$, so for some $m \in \mathbb{Z}$ we must have

$$f(x) = (x - m)(x^{n-1} + \dots - a_0/m).$$

Thus a_0/m is in \mathbb{Z} , so *m* divides a_0 .

Theorem (Eisenstein Criterion) Let $p \in \mathbb{Z}$ be a prime. Suppose that $f(x) = a_n x^n + \dots + a_0$ is in $\mathbb{Z}[x]$, and $a_n \neq 0 \pmod{p}$, but $a_i = 0 \pmod{p}$ for all i < n, with $a_0 \neq 0 \pmod{p^2}$. Then f(x) is irreducible over \mathbb{Q} .

KARPAGAM ACADEMY OF HIGHER EDUCATION CLASS: II B.Sc MATHEMATICS COURSE NAME: Ring Thory and Linear Algebra-II COURSE CODE: 16MMU403 UNIT: I BATCH-2016-2019

Proof By Theorem 23.11 we need only show that f(x) does not factor into polynomials of lower degree in $\mathbb{Z}[x]$. If

$$f(x) = (b_r x^r + \dots + b_0)(c_s x^s + \dots + c_0)$$

is a factorization in $\mathbb{Z}[x]$, with $b_r \neq 0$, $c_s \neq 0$ and r, s < n, then $a_0 \neq 0 \pmod{p^2}$ implies that b_0 and c_0 are not both congruent to 0 modulo p. Suppose that $b_0 \neq 0 \pmod{p}$ and $c_0 \equiv 0 \pmod{p}$. Now $a_n \neq 0 \pmod{p}$ implies that $b_r, c_s \neq 0 \pmod{p}$, since $a_n = b_r c_s$. Let m be the smallest value of k such that $c_k \neq 0 \pmod{p}$. Then

$$a_m = b_0 c_m + b_1 c_{m-1} + \dots + \begin{cases} b_m c_0 \text{ if } r \ge m, \\ b_r c_{m-r} \text{ if } r < m. \end{cases}$$

The fact that neither b_0 nor c_m are congruent to 0 modulo p while c_{m-1}, \dots, c_0 are all congruent to 0 modulo p implies that $a_m \neq 0$ modulo p, so m = n. Consequently, s = n, contradicting our assumption that s < n; that is, that our factorization was nontrivial.

Corollary The polynomial

$$\Phi_p(x) = \frac{x^p - 1}{x - 1} = x^{p - 1} + x^{p - 2} + \dots + x + 1$$

is irreducible over Q for any prime p.

Proof Again by Theorem 23.11, we need only consider factorizations in $\mathbb{Z}[x]$. We remarked following Theorem 22.5 that its proof actually shows that evaluation homomorphism can be used for commutative rings. Here we want to use the evaluation homomorphism $\phi_{x+1} : \mathbb{Q}[x] \to \mathbb{Q}[x]$. It is natural for us to denote $\phi_{x+1}(f(x))$ by f(x+1) for $f(x) \in \mathbb{Q}[x]$. Let

$$g(x) = \Phi_p(x+1) = \frac{(x+1)^p - 1}{(x+1) - 1} = \frac{x^p + \binom{p}{1}x^{p-1} + \dots + px}{x}.$$

The coefficient of x^{p-r} for 0 < r < p is the binomial coefficient p!/[r!(p-r)!] which is divisible by p because p divides p! but does not divide either r! or (p-r)! when 0 < r < p. Thus

$$g(x) = x^{p-1} + {p \choose 1} x^{p-2} + \dots + p$$

satisifies the Eisenstein criterion for the prime p and is thus irreducible over Q. But if $\Phi_p(x) = h(x)r(x)$ were a nontrivial factorization of $\Phi_p(x)$ in $\mathbb{Z}[x]$, then

$$\Phi_p(x+1) = g(x) = h(x+1)r(x+1)$$

would give a nontrivial factorization of g(x) in $\mathbb{Z}[x]$. Thus $\Phi_p(x)$ must also be irreducible over \mathbb{Q} .

- **Theorem** Let p(x) be an irreducible polynomial in F[x]. If p(x) divides r(x)s(x) for r(x), $s(x) \in F[x]$, then either p(x) divides r(x) or p(x) divides s(x).
- **Corollary** If p(x) is irreducible in F[x] and p(x) divides the product $r_1(x) \cdots r_n(x)$ for $r_i(x) \in F[x]$, then p(x) divides $r_i(x)$ for at least one *i*.

KARPAGAM ACADEMY OF HIGHER EDUCATION CLASS: II B.Sc MATHEMATICS COURSE NAME: Ring Thory and Linear Algebra-II

COURSE CODE: 16MMU403UNIT: IBATCH-2016-2019

- **Theorem** If \tilde{F} is a field, then every nonconstant polynomial $f(x) \in F[x]$ can be factored in F[x]into a product of irreducible polynomials, the irreducible polynomials being unique except for order and for unit (that is, nonzero constant) factors in F.
 - **Proof** Let $f(x) \in F[x]$ be a nonconstant polynomial. If f(x) is not irreducible, then f(x) = g(x)h(x), with the degree of g(x) and the degree of h(x) both less than the degree of f(x). If g(x) and h(x) are both irreducible, we stop here. If not, at least one of them factors into polynomials of lower degree. Continuing this process, we arrive at a factorization

$$f(x) = p_1(x)p_2(x)\cdots p_r(x),$$

where $p_i(x)$ is irreducible for $i = 1, 2, \dots, r$.

It remains for us to show uniqueness. Suppose that

$$f(x) = p_1(x)p_2(x)\cdots p_r(x) = q_1(x)q_2(x)\cdots q_s(x)$$

are two factorizations of f(x) into irreducible polynomials. Then by Corollary 23.19, $p_1(x)$ divides some $q_1(x)$, let us assume $q_1(x)$. Since $q_1(x)$ is irreducible,

$$q_1(x) = u_1 p_1(x),$$

where $u_1 \neq 0$, but u_1 is in F and thus is a unit. Then substituting $u_1 p_1(x)$ for $q_1(x)$ and canceling, we get

$$p_2(x)\cdots p_r(x)=u_1q_2(x)\cdots q_s(x).$$

By a similar argument, say $q_2(x) = u_2 p_2(x)$, so

$$p_3(x)\cdots p_r(x) = u_1u_2q_3(x)\cdots q_s(x).$$

Continuing in this manner, we eventually arrive at

$$1 = u_1 u_2 \cdots u_r q_{r+1}(x) \cdots q_s(x).$$

This is only possible if s = r, so that this equation is actually $1 = u_1u_2 \cdots u_r$. Thus the irreducible factors $p_i(x)$ and $q_j(x)$ were the same except possibly for order and unit factors.

Divisibility in Integral Domains Irreducibles, Primes

In the previous two chapters, we focused on factoring polynomials over the integers or a field. Several of those results, unique factorization in Z[x] and the division algorithm for F[x], for instance, are natural counterparts to theorems about the integers. In this chapter and the next, we examine factoring in a more abstract setting.

DEFINITION Associates, Irreducibles, Primes

Elements a and b of an integral domain D are called associates if a = ubwhere u is a unit of D. A nonzero element a of an integral domain D is called *irreducible* if a is not a unit and, whenever b, $c \in D$ with a = bc, then b or c is a unit. A nonzero element a of an integral domain D is called *prime* if a is not a unit and $a \mid bc$ implies $a \mid b$ or $a \mid c$.

Example 1 We exhibit an irreducible in $Z[\sqrt{-3}]$ that is not prime. Here $N(a + b\sqrt{-3}) = a^2 + 3b^2$. Consider $1 + \sqrt{-3}$. Suppose we can factor this as xy where neither x nor y is a unit. Then $N(xy) = N(x)N(y) = N(1 + \sqrt{-3}) = 4$, and it follows that N(x) = 2. But there are no integers a and b satisfying $a^2 + 3b^2 = 2$. Thus, x or y is a unit and $1 + \sqrt{-3}$ is an irreducible. To verify that it is not prime, we observe that $(1 + \sqrt{-3})(1 - \sqrt{-3}) = 4 = 2 \cdot 2$ so that $1 + \sqrt{-3}$ divides $2 \cdot 2$. On the other hand, for integers a and b to exist so that $2 = (1 + \sqrt{-3})(a + b\sqrt{-3}) = (a - 3b) + (a + b)\sqrt{-3}$, we must have a - 3b = 2 and a + b = 0, which is impossible. \Box

Theorem 20.1 Prime Implies Irreducible In an integral domain, every prime is irreducible.

Proof. Suppose a is a prime in an integral domain and a = bc. We must show that b or c is a unit. By definition of prime, we know $a \mid b$ or $a \mid c$. Say, at = b. Then $b \cdot 1 = b = at = (bc)t = b(ct)$ and, by cancellation, 1 = ct. Thus, c is a unit.

Recall that a principal ideal domain is an integral domain in which every ideal has the form $\langle a \rangle$. The next theorem reveals a circumstance in which primes and irreducibles are equivalent.

Theorem 20.2 PID Implies Irreducible Equals Prime In a principal ideal domain, an element is irreducible if and only if it is prime.

Proof. Theorem 20.1 shows primes are irreducible. To prove the converse, let a be an irreducible element of a principal ideal domain D and suppose $a \mid bc$. We must show $a \mid b$ or $a \mid c$. Consider the ideal $I = \{ax + by \mid x, b \mid x, b \mid x, b \mid x\}$

 $y \in D$ and let $\langle d \rangle = I$. Since $a \in I$, we can write a = dr, and because a is irreducible, d is a unit or r is a unit. If d is a unit, then I = D and we may write 1 = ax + by. Then c = acx + bcy, and since a divides both terms on the right, a also divides c.

On the other hand, if r is a unit, then $\langle a \rangle = \langle d \rangle = I$, and because $b \in I$, there is an element t in D such that at = b. Thus, a divides b.

Example 2 We show Z[x] is not a principal ideal domain. Consider the ideal $I = \{ax + 2b \mid a, b \in Z\}$. We claim I is not of the form $\langle h(x) \rangle$. If this were so, there would be f(x) and g(x) in Z[x] such that 2 = h(x)f(x) and x = h(x)g(x), since both 2 and x belong to I. By the degree rule (exercise 16 of Chapter 18), $0 = \deg 2 = \deg h(x) + \deg f(x)$ so that h(x) is a constant polynomial. To determine which constant, we observe 2 = h(1)f(1). Thus, $h(1) = \pm 1$ or ± 2 . Since 1 is not in I, we must have $h(x) = \pm 2$. But then $x = \pm 2g(x)$, which is nonsense.

Unique Factorization Domains

We now have the necessary terminology to formalize the idea of unique factorization.

DEFINITION Unique Factorization Domain (UFD) An integral domain D is a unique factorization domain if

- 1. every nonzero element of D that is not a unit can be written as a product of irreducibles of D, and
- 2. the factorization into irreducibles is unique up to associates and the order in which the factors appear.

Another way to formulate part 2 of this definition is the following. If $p_1^{n_1}p_2^{n_2} \ldots p_r^{n_r}$ and $q_1^{m_1}q_2^{m_2} \ldots q_s^{m_s}$ are two factorizations of some element as a product of irreducibles, where none of the p_i 's are associates and none of the q_j 's are associates, then r = s, and each $p_i^{n_i}$ is an associate of one and only one $q_j^{m_j}$.

KARPAGAM ACADEMY OF HIGHER EDUCATION CLASS: II B.Sc MATHEMATICS COURSE NAME: Ring Thory and Linear Algebra-II COURSE CODE: 16MMU403 UNIT: II BATCH-2016-2019

Lemma Ascending Chain Condition for a PID

In a principal ideal domain, any strictly increasing chain of ideals $I_1 \subset I_2 \subset \cdots$ must be finite in length.

Proof. Let $I_1 \subset I_2 \subset \cdots$ be a chain of strictly increasing ideals in an integral domain D, and let I be the union of all the ideals in this chain. We leave it as an exercise to verify that I is an ideal of D.

Then, since D is a principal ideal domain, there is an element a in D such that $I = \langle a \rangle$. Because $a \in I$ and $I = \bigcup_k I_k$, a belongs to some member of the chain, say, $a \in I_n$. Clearly, then, for any member I_i of the chain, we have $I_i \subseteq I = \langle a \rangle \subseteq I_n$ so that I_n must be the last member of the chain.

Theorem 20.3 PID Implies UFD

Every principal ideal domain is a unique factorization domain.

Proof. Let D be a principal ideal domain. We first show that any nonzero element of D that is not a unit is a product of irreducibles (the product could consist of only one factor). To do this, let a_0 be a nonzero, nonunit that is not irreducible. Then we may write $a_0 = b_1a_1$ where neither b_1 nor a_1 is a unit. Now, if both b_1 and a_1 can be written as a product of irreducibles, then so can a_0 . Thus, we may assume one of b_1 or a_1 cannot be written as a product of irreducibles, say a_1 . Then, as before, we may write $a_1 = b_2a_2$ where neither b_2 nor a_2 is a unit. Continuing in this fashion, we obtain an infinite sequence b_1, b_2, \ldots of elements that are not units in D and an infinite sequence a_0, a_1, a_2, \ldots of nonzero elements of D, with $a_n = b_{n+1}a_{n+1}$ for each n. Since b_{n+1} is not a unit, we have $\langle a_n \rangle \subset \langle a_{n+1} \rangle$ for each n (see exercise 3). Hence, $\langle a_0 \rangle \subset \langle a_1 \rangle \subset \cdots$ is an infinite strictly increasing chain of ideals. This contradicts the preceding lemma, so we conclude a_0 is, indeed, a product of irreducibles.

It remains to show that the factorization is unique up to associates and the order in which the factors appear. To do this, suppose some element a of D can be written

$$a = p_1 p_2 \ldots p_r = q_1 q_2 \ldots q_s,$$

where the p's and q's are irreducible and repetition is permitted. We induct on r. If r = 1, then a is irreducible and, clearly, s = 1 and $p_1 = q_1$. So

KARPAGAM ACADEMY OF HIGHER EDUCATION CLASS: II B.Sc MATHEMATICS COURSE NAME: Ring Thory and Linear Algebra-II COURSE CODE: 16MMU403 UNIT: II BATCH-2016-2019

we may assume that any element that can be expressed as a product of fewer than r irreducible factors can be done so in only one way (up to order and associates). Since p_1 divides $q_1q_2 \ldots q_s$, it must divide some q_i (see exercise 24), say, $p_1 | q_1$. Then, $q_1 = up_1$, where u is a unit of D. Thus,

$$ua = up_1p_2 \ldots p_r = q_1(uq_2) \ldots q_s$$

and, by cancellation,

 $p_2 \ldots p_r = (uq_2) \ldots q_s.$

The induction hypothesis now tells us that these two factorizations are identical up to associates and the order in which the factors appear. Hence, the same is true about the two factorizations of a.

Corollary F[x] Is a UFD Let F be a field. Then F[x] is a unique factorization domain.

Proof. By Theorem 18.3, F[x] is a principal ideal domain. So, F[x] is a unique factorization domain, as well.

Example 3 Let

$$f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_0 \in Z[x],$$

and suppose p is prime such that

$$p \neq a_n, p \mid a_{n-1}, \ldots, p \mid a_0,$$

and $p^2 \not\downarrow a_0$. We will prove that f(x) is irreducible over Q. If f(x) is reducible over Q, we know there exist elements g(x) and h(x) in Z[x] such that f(x) = g(x)h(x)and $1 \leq \deg g(x)$, $\deg h(x) < n$. Let $\overline{f}(x)$, $\overline{g}(x)$, and $\overline{h}(x)$ be the polynomials in $Z_p[x]$ obtained from f(x), g(x), and h(x) by reducing all coefficients modulo p. Then, since p divides all the coefficients of f(x) except a_n , we have $\overline{a_n}x^n = \overline{f}(x) = \overline{g}(x)\overline{h}(x)$. Since Z_p is a field, $Z_p[x]$ is a unique factorization domain. Thus, $x \mid \overline{g}(x)$ and $x \mid \overline{h}(x)$. So, $\overline{g}(0) = \overline{h}(0) = 0$ and, therefore, $p \mid g(0)$ and $p \mid h(0)$. But, then, $p^2 \mid g(0)h(0) = f(0) = a_0$, a contradiction.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IIBATCH-2016-2019

Euclidean Domains

Another important kind of integral domain is a Euclidean domain.

DEFINITION Euclidean Domain

An integral domain D is called a *Euclidean domain* if there is a function d from the nonzero elements of D to the nonnegative integers such that

1. $d(a) \leq d(ab)$ for all nonzero a, b in D; and

2. if $a, b \in D$, $b \neq 0$, then there exist elements q and r in D such that a = bq + r where r = 0 or d(r) < d(b).

Example 4 The ring Z is a Euclidean domain with d(a) = |a| (the absolute value of a).

Example 5 Let F be a field. Then F[x] is a Euclidean domain with $d(f(x)) = \deg f(x)$ (see Theorem 18.2).

Example 6 The ring of Gaussian integers

$$Z[i] = \{a + bi \mid a, b \in Z\}$$

is a Euclidean domain with $d(a + bi) = a^2 + b^2$. Unlike the previous two examples, the function d does not obviously satisfy the necessary conditions. That $d(x) \le d(xy)$ for $x, y \in Z[i]$ follows directly from the fact that d(xy) = d(x)d(y) (exercise 5). If $x, y \in Z[i]$ and $y \ne 0$ then $xy^{-1} \in Q[i]$, the field of quotients of Z[i] (exercise 41 of Chapter 17). Say, $xy^{-1} = s + ti$ where $s, t \in Q$. Now let m be the integer nearest s, and let n be the integer nearest t. (These integers may not be uniquely determined but that does not matter.) Thus, $|m - s| \le \frac{1}{2}$ and $|n - t| \le \frac{1}{2}$. Then

$$xy^{-1} = s + ti = (m - m + s) + (n - n + t)i$$

= (m + ni) + [(s - m) + (t - n)i].

So,

$$x = (m + ni)y + [(s - m) + (t - n)i]y.$$

Theorem 20.4 ED (Euclidean Domain) Implies PID Every Euclidean domain is a principal ideal domain.

Proof. Let D be a Euclidean domain and I a nonzero ideal of D. Among all the elements of I, let a be such that d(a) is minimum. Then $I = \langle a \rangle$. For, if $b \in I$, there are elements q and r such that b = aq + r where r = 0or d(r) < d(a). But $r = b - aq \in I$, so d(r) cannot be less than d(a). Thus, r = 0 and $b \in \langle a \rangle$.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Thory and Linear Algebra-IICOURSE CODE: 16MMU403UNIT: IIBATCH-2016-2019

Corollary ED Implies UFD Every Euclidean domain is a unique factorization domain.

We may summarize our theorems and remarks as follows:

 $ED \Rightarrow PID \Rightarrow UFD$ $UFD \not\Rightarrow PID \not\Rightarrow ED$

Theorem 20.5 D a UFD Implies D[x] a UFD If D is a unique factorization domain, then D[x] is a unique factorization.

We conclude this chapter with an example of an integral domain that is not a unique factorization domain.

Example 7 The ring $Z[\sqrt{-5}] = \{a + b\sqrt{-5} \mid a, b \in Z\}$ is an integral domain but not a unique factorization domain. It is straightforward that $Z[\sqrt{-5}]$ is an integral domain (see exercise 9 of Chapter 15). To verify that unique factorization does not hold, we mimic the method used in Example 1 with $N(a + b\sqrt{-5}) = a^2 + 5b^2$. Since N(xy) = N(x)N(y) and N(x) = 1 if and only if x is a unit (see exercise 14), it follows that the only units of $Z[\sqrt{-5}]$ are ± 1 .

Now consider the following factorizations:

$$46 = 2 \cdot 23, 46 = (1 + 3\sqrt{-5})(1 - 3\sqrt{-5}).$$

We claim that each of these four factors is irreducible over $Z[\sqrt{-5}]$. Suppose, say, 2 = xy where $x, y \in Z[\sqrt{-5}]$ and neither is a unit. Then 4 = N(2) = N(x)N(y) and, therefore, N(x) = N(y) = 2, which is impossible. Likewise, if 23 = xy were a nontrivial factorization, then N(x) = 23. Thus, there would be integers a and b such that $a^2 + 5b^2 = 23$. Clearly, no such integers exist. The same argument applies to $1 \pm 3\sqrt{-5}$.

Linear Functionals

If V is a vector space over the field F, a linear transformation f from V into the scalar field F is also called a **linear functional** on V. If we start from scratch, this means that f is a function from V into F such that

 $f(c\alpha + \beta) = cf(\alpha) + f(\beta)$

for all vectors α and β in V and all scalars c in F. The concept of linear functional is important in the study of finite-dimensional spaces because it helps to organize and clarify the discussion of subspaces, linear equations, and coordinates.

Example

Let F be a field and let a_1, \ldots, a_n be scalars in F. Define

a function f on F^n by

 $f(x_1,\ldots,x_n) = a_1x_1 + \cdots + a_nx_n.$

Then f is a linear functional on F^n . It is the linear functional which is represented by the matrix $[a_1 \cdots a_n]$ relative to the standard ordered basis for F^n and the basis $\{1\}$ for F:

 $a_j = f(\epsilon_j), \qquad j = 1, \ldots, n.$

Every linear functional on F^n is of this form, for some scalars a_1, \ldots, a_n . That is immediate from the definition of linear functional because we define $a_j = f(\epsilon_j)$ and use the linearity

•
$$f(x_1, \ldots, x_n) = f\left(\sum_j x_j \epsilon_j\right)$$
$$= \sum_j x_j f(\epsilon_j)$$
$$= \sum_j a_j x_j.$$

Example

Here is an important example of a linear functional.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Let n be a positive integer and F a field. If A is an $n \times n$ matrix with entries in F, the **trace** of A is the scalar

 $\mathrm{tr}\,A = A_{11} + A_{22} + \cdots + A_{nn}.$

The trace function is a linear functional on the matrix space $F^{n \times n}$ because

$$\operatorname{tr} (cA + B) = \sum_{i=1}^{n} (cA_{ii} + B_{ii})$$
$$= c \sum_{i=1}^{n} A_{ii} + \sum_{i=1}^{n} B_{ii}$$
$$= c \operatorname{tr} A + \operatorname{tr} B.$$

Example

Let V be the space of all polynomial functions from the

field F into itself. Let t be an element of F. If we define

 $L_t(p) = p(t)$

then L_t is a linear functional on V. One usually describes this by saying that, for each t, 'evaluation at t' is a linear functional on the space of polynomial functions. Perhaps we should remark that the fact that the functions are polynomials plays no role in this example. Evaluation at t is a linear functional on the space of all functions from F into F.

Example

This may be the most important linear functional in

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

mathematics. Let [a, b] be a closed interval on the real line and let C([a, b]) be the space of continuous real-valued functions on [a, b]. Then

$$L(g) = \int_a^b g(t) \, dt$$

defines a linear functional L on C([a, b]).

If V is a vector space, the collection of all linear functionals on V forms a vector space in a natural way. It is the space L(V, F). We denote this space by V^* and call it the **dual space** of V:

 $V^* = L(V, F).$

If V is finite-dimensional, we can obtain a rather explicit description of the dual space V^* . From Theorem 5 we know something about the space V^* , namely that

$$\dim V^* = \dim V.$$

Let $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ be a basis for V. According to Theorem 1, there is (for each *i*) a unique linear functional f_i on V such that

$$(3-11) f_i(\alpha_j) = \delta_{ij}.$$

In this way we obtain from \mathcal{B} a set of *n* distinct linear functionals f_1, \ldots, f_n on *V*. These functionals are also linearly independent. For, suppose

$$(3-12) f = \sum_{i=1}^{n} c_i f_i$$

Then

In particular, if f is the zero functional, $f(\alpha_j) = 0$ for each j and hence the scalars c_j are all 0. Now f_1, \ldots, f_n are n linearly independent functionals, and since we know that V^* has dimension n, it must be that $\mathfrak{B}^* = \{f_1, \ldots, f_n\}$ is a basis for V^* . This basis is called the **dual basis** of \mathfrak{B} .

Theorem

Let V be a finite-dimensional vector space over the field F,

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

and let $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ be a basis for V. Then there is a unique dual basis $\mathfrak{B}^* = \{f_1, \ldots, f_n\}$ for V^{*} such that $f_i(\alpha_j) = \delta_{ij}$. For each linear functional f on V we have

(3-13)
$$f = \sum_{i=1}^{n} f(\alpha_i) f_i$$

and for each vector α in V we have

(3-14)
$$\alpha = \sum_{i=1}^{n} f_i(\alpha) \alpha_i.$$

Proof. We have shown above that there is a unique basis which is 'dual' to \mathfrak{B} . If f is a linear functional on V, then f is some linear combination (3-12) of the f_i , and as we observed after (3-12) the scalars c_j must be given by $c_j = f(\alpha_j)$. Similarly, if

$$\alpha = \sum_{i=1}^n x_i \alpha_i$$

is a vector in V, then

$$f_j(\alpha) = \sum_{i=1}^n x_i f_j(\alpha_i)$$
$$= \sum_{i=1}^n x_i \delta_{ij}$$
$$= x_i$$

so that the unique expression for α as a linear combination of the α_i is

$$\alpha = \sum_{i=1}^n f_i(\alpha) \alpha_i.$$

Equation (3-14) provides us with a nice way of describing what the dual basis is. It says, if $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ is an ordered basis for V and $\mathfrak{B}^* = \{f_1, \ldots, f_n\}$ is the dual basis, then f_i is precisely the function which assigns to each vector α in V the *i*th coordinate of α relative to the ordered basis \mathfrak{B} . Thus we may also call the f_i the coordinate functions for \mathfrak{B} . The formula (3-13), when combined with (3-14) tells us the following: If f is in V^* , and we let $f(\alpha_i) = \alpha_i$, then when

 $\alpha = x_1\alpha_1 + \cdots + x_n\alpha_n$

 $(3-15) f(\alpha) = a_1 x_1 + \cdots + a_n x_n.$

In other words, if we choose an ordered basis \mathfrak{B} for V and describe each vector in V by its *n*-tuple of coordinates (x_1, \ldots, x_n) relative to \mathfrak{B} , then every linear functional on V has the form (3-15). This is the natural generalization of Example 18, which is the special case $V = F^n$ and $\mathfrak{B} = \{\epsilon_1, \ldots, \epsilon_n\}$.

EXAMPLE 22. Let V be the vector space of all polynomial functions from R into R which have degree less than or equal to 2. Let t_1 , t_2 , and t_3 be any three *distinct* real numbers, and let

$$L_i(p) = p(t_i).$$

Then L_1 , L_2 , and L_3 are linear functionals on V. These functionals are linearly independent; for, suppose

$$L = c_1 L_1 + c_2 L_2 + c_3 L_3.$$

If L = 0, i.e., if L(p) = 0 for each p in V, then applying L to the particular polynomial 'functions' 1, x, x^2 , we obtain

$$c_1 + c_2 + c_3 = 0$$

 $t_1c_1 + t_2c_2 + t_3c_3 = 0$
 $t_1^2c_1 + t_2^2c_2 + t_3^2c_3 = 0$

From this it follows that $c_1 = c_2 = c_3 = 0$, because (as a short computation shows) the matrix

$$egin{bmatrix} 1 & 1 & 1 \ t_1 & t_2 & t_3 \ t_1^2 & t_2^2 & t_3^2 \end{bmatrix}$$

is invertible when t_1 , t_2 , and t_3 are distinct. Now the L_i are independent, and since V has dimension 3, these functionals form a basis for V^* . What is the basis for V, of which this is the dual? Such a basis $\{p_1, p_2, p_3\}$ for V must satisfy

or

$$L_i(p_j) = \delta_{ij}$$

$$p_j(t_i) = \delta_{ij}.$$

These polynomial functions are rather easily seen to be
CLASS: II B.Sc MATHEMATICS	COURSE NAME: Ring	Theory and Linear Algebra II
COURSE CODE: 16MMU403	UNIT: III	BATCH-2016-2019

$p_1(x)$	~	$\frac{(x-t_2)(x-t_3)}{(t_1-t_2)(t_1-t_3)}$
$p_2(x)$	#	$rac{(x-t_1)(x-t_3)}{(t_2-t_1)(t_2-t_3)}$
$p_3(x)$	11	$\frac{(x-t_1)(x-t_2)}{(t_3-t_1)(t_3-t_2)}$

The basis $\{p_1, p_2, p_3\}$ for V is interesting, because according to (3-14) we have for each p in V

$$p = p(t_1)p_1 + p(t_2)p_2 + p(t_3)p_3.$$

Thus, if c_1 , c_2 , and c_3 are any real numbers, there is exactly one polynomial function p over R which has degree at most 2 and satisfies $p(t_j) = c_j$, j = 1, 2, 3. This polynomial function is $p = c_1p_1 + c_2p_2 + c_3p_3$.

Now let us discuss the relationship between linear functionals and subspaces. If f is a non-zero linear functional, then the rank of f is 1 because the range of f is a non-zero subspace of the scalar field and must (therefore) be the scalar field. If the underlying space V is finite-dimensional, the rank plus nullity theorem (Theorem 2) tells us that the null space N_f has dimension

$$\dim N_f = \dim V - 1.$$

In a vector space of dimension n, a subspace of dimension n - 1 is called a **hyperspace**. Such spaces are sometimes called hyperplanes or subspaces of codimension 1. Is every hyperspace the null space of a linear functional? The answer is easily seen to be yes. It is not much more difficult to show that each *d*-dimensional subspace of an *n*-dimensional space is the intersection of the null spaces of (n - d) linear functionals (Theorem 16 below).

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Definition. If V is a vector space over the field F and S is a subset of V, the **annihilator** of S is the set S⁰ of linear functionals f on V such that $f(\alpha) = 0$ for every α in S.

It should be clear to the reader that S^0 is a subspace of V^* , whether S is a subspace of V or not. If S is the set consisting of the zero vector alone, then $S^0 = V^*$. If S = V, then S^0 is the zero subspace of V^* . (This is easy to see when V is finite-dimensional.)

Theorem 16. Let V be a finite-dimensional vector space over the field F, and let W be a subspace of V. Then

$$\dim W + \dim W^0 = \dim V.$$

Proof. Let k be the dimension of W and $\{\alpha_1, \ldots, \alpha_k\}$ a basis for W. Choose vectors $\alpha_{k+1}, \ldots, \alpha_n$ in V such that $\{\alpha_1, \ldots, \alpha_n\}$ is a basis for V. Let $\{f_1, \ldots, f_n\}$ be the basis for V^* which is dual to this basis for V. The claim is that $\{f_{k+1}, \ldots, f_n\}$ is a basis for the annihilator W^0 . Certainly f_i belongs to W^0 for $i \ge k + 1$, because

$$f_i(\alpha_j) = \delta_{ij}$$

and $\delta_{ij} = 0$ if $i \ge k + 1$ and $j \le k$; from this it follows that, for $i \ge k + 1$, $f_i(\alpha) = 0$ whenever α is a linear combination of $\alpha_1, \ldots, \alpha_k$. The functionals f_{k+1}, \ldots, f_n are independent, so all we must show is that they span W^0 . Suppose f is in V^* . Now

$$f = \sum_{i=1}^{n} f(\alpha_i) f_i$$

so that if f is in W^0 we have $f(\alpha_i) = 0$ for $i \leq k$ and

$$f = \sum_{i=k+1}^n f(\alpha_i) f_i.$$

We have shown that if dim W = k and dim V = n then dim $W^0 = n - k$.

Corollary. If W is a k-dimensional subspace of an n-dimensional vector space V, then W is the intersection of (n - k) hyperspaces in V.

Proof. This is a corollary of the proof of Theorem 16 rather than its statement. In the notation of the proof, W is exactly the set of vectors α such that $f_i(\alpha) = 0$, $i = k + 1, \ldots, n$. In case k = n - 1, W is the null space of f_n .

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Corollary. If W_1 and W_2 are subspaces of a finite-dimensional vector space, then $W_1 = W_2$ if and only if $W_1^0 = W_2^0$.

Proof. If $W_1 = W_2$, then of course $W_1^0 = W_2^0$. If $W_1 \neq W_2$, then one of the two subspaces contains a vector which is not in the other. Suppose there is a vector α which is in W_2 but not in W_1 . By the previous corollaries (or the proof of Theorem 16) there is a linear functional f such that $f(\beta) = 0$ for all β in W, but $f(\alpha) \neq 0$. Then f is in W_1^0 but not in W_2^0 and $W_1^0 \neq W_2^0$.

In the next section we shall give different proofs for these two corollaries. The first corollary says that, if we select some ordered basis for the space, each k-dimensional subspace can be described by specifying (n - k)homogeneous linear conditions on the coordinates relative to that basis.

Let us look briefly at systems of homogeneous linear equations from the point of view of linear functionals. Suppose we have a system of linear equations,

$$\begin{array}{c} A_{11}x_1 + \cdots + A_{1n}x_n = 0\\ \vdots & \vdots\\ A_{m1}x_1 + \cdots + A_{mn}x_n = 0 \end{array}$$

for which we wish to find the solutions. If we let f_i , i = 1, ..., m, be the linear functional on F^n defined by

$$f_i(x_1,\ldots,x_n) = A_{i1}x_1 + \cdots + A_{in}x_n$$

then we are seeking the subspace of F^n of all α such that

 $f_i(\alpha) = 0, \qquad i = 1, \ldots, m.$

In other words, we are seeking the subspace annihilated by f_1, \ldots, f_m . Row-reduction of the coefficient matrix provides us with a systematic

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

method of finding this subspace. The *n*-tuple (A_{i1}, \ldots, A_{in}) gives the coordinates of the linear functional f_i relative to the basis which is dual to the standard basis for F^n . The row space of the coefficient matrix may thus be regarded as the space of linear functionals spanned by f_1, \ldots, f_m . The solution space is the subspace annihilated by this space of functionals.

Now one may look at the system of equations from the 'dual' point of view. That is, suppose that we are given m vectors in F^n

 $\alpha_i = (A_{i1}, \ldots, A_{in})$

and we wish to find the annihilator of the subspace spanned by these vectors. Since a typical linear functional on F^n has the form

$$f(x_1,\ldots,x_n) = c_1x_1 + \cdots + c_nx_n$$

the condition that f be in this annihilator is that

$$\sum_{j=1}^n A_{ij}c_j = 0, \qquad i = 1, \ldots, m$$

that is, that (c_1, \ldots, c_n) be a solution of the system AX = 0. From this point of view, row-reduction gives us a systematic method of finding the annihilator of the subspace spanned by a given finite set of vectors in F^n .

EXAMPLE Here are three linear functionals on R^4 :

$$f_1(x_1, x_2, x_3, x_4) = x_1 + 2x_2 + 2x_3 + x_4$$

$$f_2(x_1, x_2, x_3, x_4) = 2x_2 + x_4$$

$$f_3(x_1, x_2, x_3, x_4) = -2x_1 - 4x_3 + 3x_4.$$

The subspace which they annihilate may be found explicitly by finding the row-reduced echelon form of the matrix

$$A = \begin{bmatrix} 1 & 2 & 2 & 1 \\ 0 & 2 & 0 & 1 \\ -2 & 0 & -4 & 3 \end{bmatrix}$$

A short calculation, or a peek at Example 21 of Chapter 2, shows that

$$R = \begin{bmatrix} 1 & 0 & 2 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Therefore, the linear functionals

$$g_1(x_1, x_2, x_3, x_4) = x_1 + 2x_3$$

$$g_2(x_1, x_2, x_3, x_4) = x_2$$

$$g_3(x_1, x_2, x_3, x_4) = x_4$$

span the same subspace of $(R^4)^*$ and annihilate the same subspace of R^4 as do f_1 , f_2 , f_3 . The subspace annihilated consists of the vectors with

$$\begin{array}{rcl} x_1 = -2x_3 \\ x_2 = x_4 = 0. \end{array}$$

Let W be the subspace of R^5 which is spanned by the

vectors

EXAMPLE

$$\begin{array}{ll} \alpha_1 = (2, -2, 3, 4, -1), & \alpha_3 = (0, 0, -1, -2, 3) \\ \alpha_2 = (-1, 1, 2, 5, 2), & \alpha_4 = (1, -1, 2, 3, 0). \end{array}$$

How does one describe W^0 , the annihilator of W? Let us form the 4×5 matrix A with row vectors α_1 , α_2 , α_3 , α_4 , and find the row-reduced echelon matrix R which is row-equivalent to A:

$$A = \begin{bmatrix} 2 & -2 & 3 & 4 & -1 \\ -1 & 1 & 2 & 5 & 2 \\ 0 & 0 & -1 & -2 & 3 \\ 1 & -1 & 2 & 3 & 0 \end{bmatrix} \longrightarrow R = \begin{bmatrix} 1 & -1 & 0 & -1 & 0 \\ 0 & 0 & 1 & 2 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}.$$

If f is a linear functional on R^5 :

$$f(x_1,\ldots,x_5) = \sum_{j=1}^5 c_j x_j$$

then f is in W^0 if and only if $f(\alpha_i) = 0$, i = 1, 2, 3, 4, i.e., if and only if

$$\sum_{j=1}^{5} A_{ij} c_j = 0, \qquad 1 \le i \le 4.$$

This is equivalent to

CLASS: II B.Sc MATHEMATICS	COURSE NAME	: Ring Theory and Linear Algebra II
COURSE CODE: 16MMU403	UNIT: III	BATCH-2016-2019

 \mathbf{or}

$$\sum_{j=1}^{5} R_{ij}c_j = 0, \quad 1 \le i \le 3$$

$$c_i = c_0 = c_i = 0$$

 $c_3 + 2c_4 = 0$

 $c_5 = 0.$

We obtain all such linear functionals f by assigning arbitrary values to c_2 and c_4 , say $c_2 = a$ and $c_4 = b$, and then finding the corresponding $c_1 = a + b$, $c_3 = -2b$, $c_5 = 0$. So W^0 consists of all linear functionals f of the form

$$f(x_1, x_2, x_3, x_4, x_5) = (a + b)x_1 + ax_2 - 2bx_3 + bx_4.$$

The dimension of W^0 is 2 and a basis $\{f_1, f_2\}$ for W^0 can be found by first taking a = 1, b = 0 and then a = 0, b = 1:

$$f_1(x_1,\ldots,x_5) = x_1 + x_2$$

$$f_2(x_1,\ldots,x_5) = x_1 - 2x_3 + x_4.$$

The above general f in W^0 is $f = af_1 + bf_2$.

The Double Dual

One question about dual bases which we did not answer in the last section was whether every basis for V^* is the dual of some basis for V. One way to answer that question is to consider V^{**} , the dual space of V^* .

If α is a vector in V, then α induces a linear functional L_{α} on V^* defined by

$$L_{\alpha}(f) = f(\alpha), \quad f \text{ in } V^*.$$

The fact that L_{α} is linear is just a reformulation of the definition of linear operations in V^* :

$$L_{\alpha}(cf + g) = (cf + g)(\alpha)$$

= $(cf)(\alpha) + g(\alpha)$
= $cf(\alpha) + g(\alpha)$
= $cL_{\alpha}(f) + L_{\alpha}(g).$

If V is finite-dimensional and $\alpha \neq 0$, then $L_{\alpha} \neq 0$; in other words, there exists a linear functional f such that $f(\alpha) \neq 0$. The proof is very simple and was given in Section 3.5: Choose an ordered basis $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ for V such that $\alpha_1 = \alpha$ and let f be the linear functional which assigns to each vector in V its first coordinate in the ordered basis \mathfrak{B} .

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Theorem

Let V be a finite-dimensional vector space over the field F.

For each vector α in V define

 $L_{\alpha}(f) = f(\alpha), \quad f \quad in \quad V^*.$

The mapping $\alpha \rightarrow L_{\alpha}$ is then an isomorphism of V onto V^{**}.

Proof. We showed that for each α the function L_{α} is linear. Suppose α and β are in V and c is in F, and let $\gamma = c\alpha + \beta$. Then for each f in V^*

$$L_{\gamma}(f) = f(\gamma)$$

= $f(c\alpha + \beta)$
= $cf(\alpha) + f(\beta)$
= $cL_{\alpha}(f) + L_{\beta}(f)$

and so

$$L_{\gamma} = cL_{\alpha} + L_{\beta}.$$

This shows that the mapping $\alpha \to L_{\alpha}$ is a linear transformation from V into V^{**} . This transformation is non-singular; for, according to the remarks above $L_{\alpha} = 0$ if and only if $\alpha = 0$. Now $\alpha \to L_{\alpha}$ is a non-singular linear transformation from V into V^{**} , and since

$$\lim V^{**} = \dim V^* = \dim V$$

Theorem 9 tells us that this transformation is invertible, and is therefore an isomorphism of V onto V^{**} .

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Corollary. Let V be a finite-dimensional vector space over the field F. If L is a linear functional on the dual space V^* of V, then there is a unique vector α in V such that

$$L(f) = f(\alpha)$$

for every f in V*.

Corollary. Let V be a finite-dimensional vector space over the field F. Each basis for V* is the dual of some basis for V.

Proof. Let $\mathfrak{B}^* = \{f_1, \ldots, f_n\}$ be a basis for V^* . By Theorem 15, there is a basis $\{L_1, \ldots, L_n\}$ for V^{**} such that

 $L_i(f_j) = \delta_{ij}.$

Using the corollary above, for each *i* there is a vector α_i in V such that

 $L_i(f) = f(\alpha_i)$

for every f in V^* , i.e., such that $L_i = L_{\alpha_i}$. It follows immediately that $\{\alpha_1, \ldots, \alpha_n\}$ is a basis for V and that \mathfrak{B}^* is the dual of this basis.

Theorem

If S is any subset of a finite-dimensional vector space V, then (S⁰)^o is the subspace spanned by S.

Proof. Let W be the subspace spanned by S. Clearly $W^0 = S^0$. Therefore, what we are to prove is that $W = W^{00}$. We have given one proof. Here is another. By Theorem 16

 $\dim W + \dim W^0 = \dim V$ $\dim W^0 + \dim W^{00} = \dim V^*$

and since dim $V = \dim V^*$ we have

 $\dim W = \dim W^{00}.$

Since W is a subspace of W^{00} , we see that $W = W^{00}$.

The results of this section hold for arbitrary vector spaces; however, the proofs require the use of the so-called Axiom of Choice. We want to avoid becoming embroiled in a lengthy discussion of that axiom, so we shall not tackle annihilators for general vector spaces. But, there are two results about linear functionals on arbitrary vector spaces which are so fundamental that we should include them.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Definition. If V is a vector space, a hyperspace in V is a maximal proper subspace of V.

Theorem

If f is a non-zero linear functional on the vector space V, then the null space of f is a hyperspace in V. Conversely, every hyperspace in V is the null space of a (not unique) non-zero linear functional on V.

Proof. Let f be a non-zero linear functional on V and N_f its null space. Let α be a vector in V which is not in N_f , i.e., a vector such that $f(\alpha) \neq 0$. We shall show that every vector in V is in the subspace spanned by N_f and α . That subspace consists of all vectors

$$\gamma + c\alpha$$
, $\gamma \text{ in } N_f$, $c \text{ in } F$.

Let β be in V. Define

$$c = \frac{f(\beta)}{f(\alpha)}$$

which makes sense because $f(\alpha) \neq 0$. Then the vector $\gamma = \beta - c\alpha$ is in N_f since

$$f(\gamma) = f(\beta - c\alpha)$$

= $f(\beta) - cf(\alpha)$
= 0.

So β is in the subspace spanned by N_f and α .

Now let N be a hyperspace in V. Fix some vector α which is not in N. Since N is a maximal proper subspace, the subspace spanned by N and α is the entire space V. Therefore each vector β in V has the form

 $\beta = \gamma + c\alpha, \qquad \gamma \text{ in } N, c \text{ in } F.$

The vector γ and the scalar c are uniquely determined by β . If we have also

$$\beta = \gamma' + c'\alpha, \qquad \gamma' \text{ in } N, c' \text{ in } F.$$

then

$$(c'-c)\alpha = \gamma - \gamma'.$$

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

If $c' - c \neq 0$, then α would be in N; hence, c' = c and $\gamma' = \gamma$. Another way to phrase our conclusion is this: If β is in V, there is a unique scalar c such that $\beta - c\alpha$ is in N. Call that scalar $g(\beta)$. It is easy to see that g is a linear functional on V and that N is the null space of g.

Lemma. If f and g are linear functionals on a vector space V, then g is a scalar multiple of f if and only if the null space of g contains the null space of f, that is, if and only if $f(\alpha) = 0$ implies $g(\alpha) = 0$.

Proof. If f = 0 then g = 0 as well and g is trivially a scalar multiple of f. Suppose $f \neq 0$ so that the null space N_f is a hyperspace in V. Choose some vector α in V with $f(\alpha) \neq 0$ and let

$$c = \frac{g(\alpha)}{f(\alpha)}$$

The linear functional h = g - cf is 0 on N_f , since both f and g are 0 there, and $h(\alpha) = g(\alpha) - cf(\alpha) = 0$. Thus h is 0 on the subspace spanned by N_f and α —and that subspace is V. We conclude that h = 0, i.e., that g = cf.

Theorem Let g, f_1, \ldots, f_r be linear functionals on a vector space V

with respective null spaces N, N_1, \ldots, N_r . Then g is a linear combination of f_1, \ldots, f_r if and only if N contains the intersection $N_1 \cap \cdots \cap N_r$.

Proof. If $g = c_1f_1 + \cdots + c_rf_r$ and $f_i(\alpha) = 0$ for each *i*, then clearly $g(\alpha) = 0$. Therefore, N contains $N_1 \cap \cdots \cap N_r$.

We shall prove the converse (the 'if' half of the theorem) by induction on the number r. The preceding lemma handles the case r = 1. Suppose we know the result for r = k - 1, and let f_1, \ldots, f_k be linear functionals with null spaces N_1, \ldots, N_k such that $N_1 \cap \cdots \cap N_k$ is contained in N, the

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

null space of g. Let $g', f'_1, \ldots, f'_{k-1}$ be the restrictions of g, f_1, \ldots, f_{k-1} to the subspace N_k . Then $g', f'_1, \ldots, f'_{k-1}$ are linear functionals on the vector space N_k . Furthermore, if α is a vector in N_k and $f'_i(\alpha) = 0$, $i = 1, \ldots, k - 1$, then α is in $N_1 \cap \cdots \cap N_k$ and so $g'(\alpha) = 0$. By the induction hypothesis (the case r = k - 1), there are scalars c_i such that

$$g' = c_1 f'_1 + \cdots + c_{k-1} f'_{k-1}.$$

Now let

(3-16)
$$h = g - \sum_{i=1}^{k-1} c_i f_i.$$

Then h is a linear functional on V and (3-16) tells us that $h(\alpha) = 0$ for every α in N_k . By the preceding lemma, h is a scalar multiple of f_k . If $h = c_k f_k$, then

$$g = \sum_{i=1}^{k} c_i f_i.$$

The Transpose of a Linear Transformation

Suppose that we have two vector spaces over the field F, V, and W, and a linear transformation T from V into W. Then T induces a linear transformation from W^* into V^* , as follows. Suppose g is a linear functional on W, and let

$$(3-17) f(\alpha) = g(T\alpha)$$

for each α in V. Then (3-17) defines a function f from V into F, namely, the composition of T, a function from V into W, with g, a function from W into F. Since both T and g are linear, Theorem 6 tells us that f is also linear, i.e., f is a linear functional on V. Thus T provides us with a rule T^t which associates with each linear functional g on W a linear functional $f = T^t g$ on V, defined by (3-17). Note also that T^t is actually a linear transformation from W* into V*; for, if g_1 and g_2 are in W* and c is a scalar

$$[T^{i}(cg_{1} + g_{2})](\alpha) = (cg_{1} + g_{2})(T\alpha) = cg_{1}(T\alpha) + g_{2}(T\alpha) = c(T^{i}g_{1})(\alpha) + (T^{i}g_{2})(\alpha)$$

Theorem

Let V and W be vector spaces over the field F, and let T

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

be a linear transformation from V into W. The null space of T^t is the annihilator of the range of T. If V and W are finite-dimensional, then

- (i) rank (T⁶) = rank (T)
- (ii) the range of T^t is the annihilator of the null space of T.

Proof. If g is in W^* , then by definition

 $(T^t g)(\alpha) = g(T\alpha)$

for each α in V. The statement that g is in the null space of T^{t} means that $g(T\alpha) = 0$ for every α in V. Thus the null space of T^{t} is precisely the annihilator of the range of T.

Suppose that V and W are finite-dimensional, say dim V = n and dim W = m. For (i): Let r be the rank of T, i.e., the dimension of the range of T. By Theorem 16, the annihilator of the range of T then has dimension (m - r). By the first statement of this theorem, the nullity of T^t must be (m - r). But then since T^t is a linear transformation on an m-dimensional space, the rank of T^t is m - (m - r) = r, and so T and T^t have the same rank. For (ii): Let N be the null space of T. Every functional in the range of T^t is in the annihilator of N; for, suppose $f = T^t g$ for some g in W^* ; then, if α is in N

$$f(\alpha) = (T^{t}g)(\alpha) = g(T\alpha) = g(0) = 0.$$

Now the range of T^{t} is a subspace of the space N^{0} , and

 $\dim N^{0} = n - \dim N = \operatorname{rank} (T) = \operatorname{rank} (T')$

so that the range of T^t must be exactly N^0 . **Theorem**

Let V and W be finite-dimensional vector spaces over the

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

field F. Let B be an ordered basis for V with dual basis B^{*}, and let B' be an ordered basis for W with dual basis B'*. Let T be a linear transformation from V into W; let A be the matrix of T relative to B, B' and let B be the matrix of T^t relative to B'*, B^{*}. Then $B_{ij} = A_{ji}$.

Proof. Let

$$\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}, \qquad \mathfrak{B}' = \{\beta_1, \ldots, \beta_m\}, \\ \mathfrak{B}^* = \{f_1, \ldots, f_n\}, \qquad \mathfrak{B}'^* = \{g_1, \ldots, g_m\}.$$

By definition,

$$T\alpha_j = \sum_{i=1}^m A_{ij}\beta_i, \qquad j = 1, \dots, n$$
$$T^i g_j = \sum_{i=1}^n B_{ij}f_i, \qquad j = 1, \dots, m.$$

On the other hand,

$$(T^{t}g_{j})(\alpha_{i}) = g_{j}(T\alpha_{i})$$

$$= g_{j}\left(\sum_{k=1}^{m} A_{ki}\beta_{k}\right)$$

$$= \sum_{k=1}^{m} A_{ki}g_{j}(\beta_{k})$$

$$= \sum_{k=1}^{m} A_{ki}\delta_{jk}$$

$$= A_{ii}.$$

For any linear functional f on V

$$f = \sum_{i=1}^m f(\alpha_i) f_i.$$

If we apply this formula to the functional $f = T^{t}g_{j}$ and use the fact that $(T^{t}g_{j})(\alpha_{i}) = A_{ji}$, we have

$$T^t g_j = \sum_{i=1}^n A_{ji} f_i$$

from which it immediately follows that $B_{ij} = A_{ji}$.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Definition. If A is an m \times n matrix over the field F, the transpose of A is the n \times m matrix A^t defined by $A_{ij}^t = A_{ji}$.

Theorem 23 thus states that if T is a linear transformation from V into W, the matrix of which in some pair of bases is A, then the transpose transformation T^t is represented in the dual pair of bases by the transpose matrix A^t .

Theorem 24. Let A be any $m \times n$ matrix over the field F. Then the row rank of A is equal to the column rank of A.

Proof. Let \mathfrak{B} be the standard ordered basis for F^n and \mathfrak{B}' the standard ordered basis for F^m . Let T be the linear transformation from F^n into F^m such that the matrix of T relative to the pair \mathfrak{B} , \mathfrak{B}' is A, i.e.,

$$T(x_1,\ldots,x_n) = (y_1,\ldots,y_m)$$

where

$$y_i = \sum_{j=1}^n A_{ij} x_j.$$

The column rank of A is the rank of the transformation T, because the range of T consists of all *m*-tuples which are linear combinations of the column vectors of A.

Relative to the dual bases \mathfrak{B}'^* and \mathfrak{B}^* , the transpose mapping T^t is represented by the matrix A^t . Since the columns of A^t are the rows of A, we see by the same reasoning that the row rank of A (the column rank of A^t) is equal to the rank of T^t . By Theorem 22, T and T^t have the same rank, and hence the row rank of A is equal to the column rank of A.

Now we see that if A is an $m \times n$ matrix over F and T is the linear transformation from F^n into F^m defined above, then

 $\operatorname{rank}(T) = \operatorname{row}\operatorname{rank}(A) = \operatorname{column}\operatorname{rank}(A)$

and we shall call this number simply the **rank** of A.

EXAMPLE Let V be an n-dimensional vector space over the

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

field F, and let T be a linear operator on V. Suppose $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ is an ordered basis for V. The matrix of T in the ordered basis \mathfrak{B} is defined to be the $n \times n$ matrix A such that

$$T\alpha_j = \sum_{j=1}^n A_{ij}\alpha_i$$

in other words, A_{ij} is the *i*th coordinate of the vector $T\alpha_j$ in the ordered basis \mathcal{B} . If $\{f_1, \ldots, f_n\}$ is the dual basis of \mathcal{B} , this can be stated simply

$$\Lambda_{ij} = f_i(T\alpha_j).$$

Let us see what happens when we change basis. Suppose

$$\mathfrak{B}' = \{\alpha'_1, \ldots, \alpha'_n\}$$

is another ordered basis for V, with dual basis $\{f'_1, \ldots, f'_n\}$. If B is the matrix of T in the ordered basis \mathfrak{B}' , then

$$B_{ij} = f_i'(T\alpha_j').$$

Let U be the invertible linear operator such that $U\alpha_j = \alpha'_j$. Then the transpose of U is given by $U^t f'_i = f_i$. It is easy to verify that since U is invertible, so is U^t and $(U^t)^{-1} = (U^{-1})^t$. Thus $f'_i = (U^{-1})^t f_i$, $i = 1, \ldots, n$. Therefore,

$$B_{ij} = [(U^{-1})^{t}f_{i}](T\alpha'_{j}) = f_{i}(U^{-1}T\alpha'_{j}) = f_{i}(U^{-1}TU\alpha_{j}).$$

Now what does this say? Well, $f_i(U^{-1}TU\alpha_j)$ is the *i*, *j* entry of the matrix of $U^{-1}TU$ in the ordered basis \mathfrak{B} . Our computation above shows that this scalar is also the *i*, *j* entry of the matrix of *T* in the ordered basis \mathfrak{B}' . In other words

$$[T]_{\mathfrak{B}'} = [U^{-1}TU]_{\mathfrak{B}} = [U^{-1}]_{\mathfrak{B}}[T]_{\mathfrak{B}}[U]_{\mathfrak{B}} = [U]_{\overline{\mathfrak{B}}}^{-1}[T]_{\mathfrak{B}}[U]_{\mathfrak{B}}$$

and this is precisely the change-of-basis formula which we derived earlier.

Eigen space of a Linear operator:

Characteristic Values

Definition. Let V be a vector space over the field F and let T be a linear operator on V. A characteristic value of T is a scalar c in F such that there is a non-zero vector α in V with $T\alpha = c\alpha$. If c is a characteristic value of T, then

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

(a) any α such that $T\alpha = c\alpha$ is called a characteristic vector of T associated with the characteristic value c;

(b) the collection of all α such that $T\alpha = c\alpha$ is called the **characteristic** space associated with c.

Characteristic values are often called characteristic roots, latent roots, eigenvalues, proper values, or spectral values. In this book we shall use only the name 'characteristic values.'

If T is any linear operator and c is any scalar, the set of vectors α such that $T\alpha = c\alpha$ is a subspace of V. It is the null space of the linear transformation (T - cI). We call c a characteristic value of T if this subspace is different from the zero subspace, i.e., if (T - cI) fails to be 1:1. If the underlying space V is finite-dimensional, (T - cI) fails to be 1:1 precisely when its determinant is different from 0. Let us summarize.

Theorem Let T be a linear operator on a finite-dimensional space V and let c be a scalar. The following are equivalent.

- (i) c is a characteristic value of T.
- (ii) The operator (T cI) is singular (not invertible).
- (iii) det (T cI) = 0.

The determinant criterion (iii) is very important because it tells us where to look for the characteristic values of T. Since det (T - cI) is a polynomial of degree n in the variable c, we will find the characteristic values as the roots of that polynomial. Let us explain carefully.

If \mathfrak{B} is any ordered basis for V and $A = [T]_{\mathfrak{B}}$, then (T - cI) is invertible if and only if the matrix (A - cI) is invertible. Accordingly, we make the following definition.

Definition. If A is an $n \times n$ matrix over the field F, a characteristic value of A in F is a scalar c in F such that the matrix (A - cI) is singular (not invertible).

Since c is a characteristic value of A if and only if det (A - cI) = 0, or equivalently if and only if det (cI - A) = 0, we form the matrix (xI - A) with polynomial entries, and consider the polynomial f =det (xI - A). Clearly the characteristic values of A in F are just the scalars c in F such that f(c) = 0. For this reason f is called the **characteristic polynomial** of A. It is important to note that f is a monic polynomial which has degree exactly n. This is easily seen from the formula for the determinant of a matrix in terms of its entries.

KARPAGAM ACADEMY OF HIGHER EDUCATIONCLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Lemma. Similar matrices have the same characteristic polynomial.

Proof. If
$$B = P^{-1}AP$$
, then
det $(xI - B) = \det (xI - P^{-1}AP)$
 $= \det (P^{-1}(xI - A)P)$
 $= \det P^{-1} \cdot \det (xI - A) \cdot \det P$
 $= \det (xI - A).$

This lemma enables us to define sensibly the characteristic polynomial of the operator T as the characteristic polynomial of any $n \times n$ matrix which represents T in some ordered basis for V. Just as for matrices, the characteristic values of T will be the roots of the characteristic polynomial or T. In particular, this shows us that T cannot have more than n distinct characteristic values. It is important to point out that T may not have any characteristic values.

EXAMPLE Let T be the linear operator on \mathbb{R}^2 which is represented

in the standard ordered basis by the matrix

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}.$$

The characteristic polynomial for T (or for A) is

det
$$(xI - A) = \begin{vmatrix} x & 1 \\ -1 & x \end{vmatrix} = x^2 + 1.$$

Since this polynomial has no real roots, T has no characteristic values. If U is the linear operator on C^2 which is represented by A in the standard ordered basis, then U has two characteristic values, i and -i. Here we see a subtle point. In discussing the characteristic values of a matrix A, we must be careful to stipulate the field involved. The matrix A above has no characteristic values in R, but has the two characteristic values i and -i in C.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

EXAMPLE Let A be the (real) 3×3 matrix

$$\begin{bmatrix} 3 & 1 & -1 \\ 2 & 2 & -1 \\ 2 & 2 & 0 \end{bmatrix}$$

Then the characteristic polynomial for A is

$$\begin{vmatrix} x-3 & -1 & 1 \\ -2 & x-2 & 1 \\ -2 & -2 & x \end{vmatrix} = x^3 - 5x^2 + 8x - 4 = (x-1)(x-2)^2.$$

Thus the characteristic values of A are 1 and 2.

Suppose that T is the linear operator on R^3 which is represented by A in the standard basis. Let us find the characteristic vectors of T associated with the characteristic values, 1 and 2. Now

$$A - I = \begin{bmatrix} 2 & 1 & -1 \\ 2 & 1 & -1 \\ 2 & 2 & -1 \end{bmatrix}.$$

It is obvious at a glance that A - I has rank equal to 2 (and hence T - I has nullity equal to 1). So the space of characteristic vectors associated with the characteristic value 1 is one-dimensional. The vector $\alpha_1 = (1, 0, 2)$ spans the null space of T - I. Thus $T\alpha = \alpha$ if and only if α is a scalar multiple of α_1 . Now consider

$$A - 2I = \begin{bmatrix} 1 & 1 & -1 \\ 2 & 0 & -1 \\ 2 & 2 & -2 \end{bmatrix}$$

KARPAGAM ACADEMY OF HIGHER EDUCATIONCLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Evidently A - 2I also has rank 2, so that the space of characteristic vectors associated with the characteristic value 2 has dimension 1. Evidently $T\alpha = 2\alpha$ if and only if α is a scalar multiple of $\alpha_2 = (1, 1, 2)$.

Definition. Let T be a linear operator on the finite-dimensional space. V. We say that T is **diagonalizable** if there is a basis for V each vector of which is a characteristic vector of T.

The reason for the name should be apparent; for, if there is an ordered basis $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ for V in which each α_i is a characteristic vector of T, then the matrix of T in the ordered basis \mathfrak{B} is diagonal. If $T\alpha_i = c_i\alpha_i$, then

 $[T]_{\mathfrak{B}} = \begin{bmatrix} c_1 & 0 & \cdots & 0 \\ 0 & c_2 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & c_n \end{bmatrix}.$

We certainly do not require that the scalars c_1, \ldots, c_n be distinct; indeed, they may all be the same scalar (when T is a scalar multiple of the identity operator).

One could also define T to be diagonalizable when the characteristic vectors of T span V. This is only superficially different from our definition, since we can select a basis out of any spanning set of vectors.

Lemma. Let T be a linear operator on the finite-dimensional space V. Let c_1, \ldots, c_k be the distinct characteristic values of T and let W_i be the space of characteristic vectors associated with the characteristic value c_i . If $W = W_1 + \cdots + W_k$, then

 $\dim W = \dim W_1 + \cdots + \dim W_k.$

In fact, if \mathfrak{B}_i is an ordered basis for W_i , then $\mathfrak{B} = (\mathfrak{B}_1, \ldots, \mathfrak{B}_k)$ is an ordered basis for W.

Proof. The space $W = W_1 + \cdots + W_k$ is the subspace spanned by all of the characteristic vectors of T. Usually when one forms the sum W of subspaces W_i , one expects that dim $W < \dim W_1 + \cdots + \dim W_k$ because of linear relations which may exist between vectors in the various spaces. This lemma states that the characteristic spaces associated with different characteristic values are independent of one another.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Suppose that (for each *i*) we have a vector β_i in W_i , and assume that $\beta_1 + \cdots + \beta_k = 0$. We shall show that $\beta_i = 0$ for each *i*. Let *f* be any polynomial. Since $T\beta_i = c_i\beta_i$, the preceding lemma tells us that

$$0 = f(T)0 = f(T)\beta_1 + \cdots + f(T)\beta_k$$

= $f(c_1)\beta_1 + \cdots + f(c_k)\beta_k.$

Choose polynomials f_1, \ldots, f_k such that

$$f_i(c_j) = \delta_{ij} = \begin{cases} 1, & i = j \\ 0, & i \neq j. \end{cases}$$

Then

$$0 = f_i(T)0 = \sum_j \delta_{ij}\beta_j$$
$$= \beta_i.$$

Now, let \mathfrak{B}_i be an ordered basis for W_i , and let \mathfrak{B} be the sequence $\mathfrak{B} = (\mathfrak{B}_1, \ldots, \mathfrak{B}_k)$. Then \mathfrak{B} spans the subspace $W = W_1 + \cdots + W_k$. Also, \mathfrak{B} is a linearly independent sequence of vectors, for the following reason. Any linear relation between the vectors in \mathfrak{B} will have the form $\beta_1 + \cdots + \beta_k = 0$, where β_i is some linear combination of the vectors in \mathfrak{B}_i . From what we just did, we know that $\beta_i = 0$ for each *i*. Since each \mathfrak{B}_i is linearly independent, we see that we have only the trivial linear relation between the vectors in \mathfrak{B} .

Theorem Let T be a linear operator on a finite-dimensional space V. Let c_1, \ldots, c_k be the distinct characteristic values of T and let W_i be the null space of $(T - c_iI)$. The following are equivalent.

- (i) T is diagonalizable.
- (ii) The characteristic polynomial for T is

$$\mathbf{f} = (\mathbf{x} - \mathbf{c}_1)^{\mathbf{d}_1} \cdots (\mathbf{x} - \mathbf{c}_k)^{\mathbf{d}_k}$$

and dim $W_i = d_i$, i = 1, ..., k. (iii) dim $W_1 + \cdots + dim W_k = dim V$.

Proof. We have observed that (i) implies (ii). If the characteristic polynomial f is the product of linear factors, as in (ii), then $d_1 + \cdots + d_k = \dim V$. For, the sum of the d_i 's is the degree of the characteristic polynomial, and that degree is dim V. Therefore (ii) implies (iii). Suppose (iii) holds. By the lemma, we must have $V = W_1 + \cdots + W_k$, i.e., the characteristic vectors of T span V.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

The matrix analogue of Theorem 2 may be formulated as follows. Let A be an $n \times n$ matrix with entries in a field F, and let c_1, \ldots, c_k be the distinct characteristic values of A in F. For each i, let W_i be the space of column matrices X (with entries in F) such that

$$(A - c_i I)X = 0,$$

and let \mathfrak{B}_i be an ordered basis for W_i . The bases $\mathfrak{B}_1, \ldots, \mathfrak{B}_k$ collectively string together to form the sequence of columns of a matrix P:

$$P = [P_1, P_2, \ldots] = (\mathfrak{R}_1, \ldots, \mathfrak{R}_k).$$

The matrix A is similar over F to a diagonal matrix if and only if P is a square matrix. When P is square, P is invertible and $P^{-1}AP$ is diagonal.

EXAMPLE 3. Let T be the linear operator on R^3 which is represented in the standard ordered basis by the matrix

$$A = \begin{bmatrix} 5 & -6 & -6 \\ -1 & 4 & 2 \\ 3 & -6 & -4 \end{bmatrix}$$

Let us indicate how one might compute the characteristic polynomial, using various row and column operations:

$$\begin{vmatrix} x-5 & 6 & 6 \\ 1 & x-4 & -2 \\ -3 & 6 & x+4 \end{vmatrix} = \begin{vmatrix} x-5 & 0 & 6 \\ 1 & x-2 & -2 \\ -3 & 2-x & x+4 \end{vmatrix}$$
$$= (x-2) \begin{vmatrix} x-5 & 0 & 6 \\ 1 & 1 & -2 \\ -3 & -1 & x+4 \end{vmatrix}$$
$$= (x-2) \begin{vmatrix} x-5 & 0 & 6 \\ 1 & 1 & -2 \\ -2 & 0 & x+2 \end{vmatrix}$$
$$= (x-2) \begin{vmatrix} x-5 & 0 & 6 \\ 1 & 1 & -2 \\ -2 & 0 & x+2 \end{vmatrix}$$
$$= (x-2) \begin{vmatrix} x-5 & 6 \\ -2 & x+2 \end{vmatrix}$$
$$= (x-2)(x^2 - 3x + 2)$$
$$= (x-2)^2(x-1).$$

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

What are the dimensions of the spaces of characteristic vectors associated with the two characteristic values? We have

$$A - I = \begin{bmatrix} 4 & -6 & -6 \\ -1 & 3 & 2 \\ 3 & -6 & -5 \end{bmatrix}$$
$$A - 2I = \begin{bmatrix} 3 & -6 & -6 \\ -1 & 2 & 2 \\ 3 & -6 & -6 \end{bmatrix}.$$

We know that A - I is singular and obviously rank $(A - I) \ge 2$. Therefore, rank (A - I) = 2. It is evident that rank (A - 2I) = 1.

Let W_1 , W_2 be the spaces of characteristic vectors associated with the characteristic values 1, 2. We know that dim $W_1 = 1$ and dim $W_2 = 2$. By Theorem 2, T is diagonalizable. It is easy to exhibit a basis for R^3 in which T is represented by a diagonal matrix. The null space of (T - I) is spanned

by the vector $\alpha_1 = (3, -1, 3)$ and so $\{\alpha_1\}$ is a basis for W_1 . The null space of T - 2I (i.e., the space W_2) consists of the vectors (x_1, x_2, x_3) with $x_1 = 2x_2 + 2x_3$. Thus, one example of a basis for W_2 is

$$\alpha_2 = (2, 1, 0)$$

 $\alpha_3 = (2, 0, 1)$

If $\mathfrak{B} = \{\alpha_1, \alpha_2, \alpha_3\}$, then $[T]_{\mathfrak{B}}$ is the diagonal matrix

$$D = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix}$$

The fact that T is diagonalizable means that the original matrix A is similar (over R) to the diagonal matrix D. The matrix P which enables us to change coordinates from the basis \mathfrak{B} to the standard basis is (of course) the matrix which has the transposes of α_1 , α_2 , α_3 as its column vectors:

$$P = \begin{bmatrix} 3 & 2 & 2 \\ -1 & 1 & 0 \\ 3 & 0 & 1 \end{bmatrix}$$

Furthermore, AP = PD, so that

$$P^{-1}AP = D.$$

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Definition. Let T be a linear operator on a finite-dimensional vector space V over the field F. The **minimal polynomial** for T is the (unique) monic generator of the ideal of polynomials over F which annihilate T.

The name 'minimal polynomial' stems from the fact that the generator of a polynomial ideal is characterized by being the monic polynomial of minimum degree in the ideal. That means that the minimal polynomial pfor the linear operator T is uniquely determined by these three properties:

(1) p is a monic polynomial over the scalar field F.

(2) p(T) = 0.

(3) No polynomial over F which annihilates T has smaller degree than p has.

If A is an $n \times n$ matrix over F, we define the **minimal polynomial** for A in an analogous way, as the unique monic generator of the ideal of all polynomials over F which annihilate A. If the operator T is represented in some ordered basis by the matrix A, then T and A have the same minimal polynomial. That is because f(T) is represented in the basis by the matrix f(A), so that f(T) = 0 if and only if f(A) = 0.

From the last remark about operators and matrices it follows that similar matrices have the same minimal polynomial. That fact is also clear from the definitions because

$$f(P^{-1}AP) = P^{-1}f(A)P$$

for every polynomial f.

Theorem Let T be a linear operator on an n-dimensional vector

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

space V [or, let A be an $n \times n$ matrix]. The characteristic and minimal polynomials for T [for A] have the same roots, except for multiplicities.

Proof. Let p be the minimal polynomial for T. Let c be a scalar. What we want to show is that p(c) = 0 if and only if c is a characteristic value of T.

First, suppose p(c) = 0. Then

p = (x - c)q

where q is a polynomial. Since deg $q < \deg p$, the definition of the minimal polynomial p tells us that $q(T) \neq 0$. Choose a vector β such that $q(T)\beta \neq 0$. Let $\alpha = q(T)\beta$. Then

$$D = p(T)\beta$$

= $(T - cI)q(T)\beta$
= $(T - cI)\alpha$

and thus, c is a characteristic value of T.

Now, suppose that c is a characteristic value of T, say, $T\alpha = c\alpha$ with $\alpha \neq 0$. As we noted in a previous lemma,

$$p(T)\alpha = p(c)\alpha.$$

Since p(T) = 0 and $\alpha \neq 0$, we have p(c) = 0.

Let T be a diagonalizable linear operator and let c_1, \ldots, c_k be the distinct characteristic values of T. Then it is easy to see that the minimal polynomial for T is the polynomial

$$p = (x - c_1) \cdots (x - c_k).$$

If α is a characteristic vector, then one of the operators $T - c_1 I, \ldots, T - c_k I$ sends α into 0. Therefore

$$(T-c_1I)\cdots(T-c_kI)\alpha=0$$

for every characteristic vector α . There is a basis for the underlying space which consists of characteristic vectors of T; hence

$$p(T) = (T - c_1 I) \cdots (T - c_k I) = 0.$$

What we have concluded is this. If T is a diagonalizable linear operator, then the minimal polynomial for T is a product of distinct linear factors. As we shall soon see, that property characterizes diagonalizable operators.

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

EXAMPLE Let's try to find the minimal polynomials for the operators in Examples 1, 2, and 3. We shall discuss them in reverse order. The operator in Example 3 was found to be diagonalizable with characteristic polynomial

$$f = (x - 1)(x - 2)^2$$
.

From the preceding paragraph, we know that the minimal polynomial for T is

$$p = (x-1)(x-2).$$

The reader might find it reassuring to verify directly that

$$(A - I)(A - 2I) = 0.$$

In Example 2, the operator T also had the characteristic polynomial $f = (x - 1)(x - 2)^2$. But, this T is not diagonalizable, so we don't know that the minimal polynomial is (x - 1) (x - 2). What do we know about the minimal polynomial in this case? From Theorem 3 we know that its roots are 1 and 2, with some multiplicities allowed. Thus we search for p among polynomials of the form $(x - 1)^k (x - 2)^l$, $k \ge 1$, $l \ge 1$. Try (x - 1) (x - 2):

$$(A - I)(A - 2I) = \begin{bmatrix} 2 & 1 & -1 \\ 2 & 1 & -1 \\ 2 & 2 & -1 \end{bmatrix} \begin{bmatrix} 1 & 1 & -1 \\ 2 & 0 & -1 \\ 2 & 2 & -2 \end{bmatrix}$$
$$= \begin{bmatrix} 2 & 0 & -1 \\ 2 & 0 & -1 \\ 4 & 0 & -2 \end{bmatrix} \cdot$$

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Thus, the minimal polynomial has degree at least 3. So, next we should try either $(x - 1)^2(x - 2)$ or $(x - 1)(x - 2)^2$. The second, being the characteristic polynomial, would seem a less random choice. One can readily compute that $(A - I)(A - 2I)^2 = 0$. Thus the minimal polynomial for T is its characteristic polynomial.

In Example 1 we discussed the linear operator T on R^2 which is represented in the standard basis by the matrix

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

The characteristic polynomial is $x^2 + 1$, which has no real roots. To determine the minimal polynomial, forget about T and concentrate on A. As a complex 2×2 matrix, A has the characteristic values i and -i. Both roots must appear in the minimal polynomial. Thus the minimal polynomial is divisible by $x^2 + 1$. It is trivial to verify that $A^2 + I = 0$. So the minimal polynomial is $x^2 + 1$.

Theorem 4 (Cayley-Hamilton). Let T be a linear operator on a finite dimensional vector space V. If f is the characteristic polynomial for T, then f(T) = 0; in other words, the minimal polynomial divides the characteristic polynomial for T.

Proof. Later on we shall give two proofs of this result independent of the one to be given here. The present proof, although short, may be difficult to understand. Aside from brevity, it has the virtue of providing

KARPAGAM ACADEMY OF HIGHER EDUCATIONCLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

an illuminating and far from trivial application of the general theory of determinants developed in Chapter 5.

Let K be the commutative ring with identity consisting of all polynomials in T. Of course, K is actually a commutative algebra with identity over the scalar field. Choose an ordered basis $\{\alpha_1, \ldots, \alpha_n\}$ for V, and let A be the matrix which represents T in the given basis. Then

$$T\alpha_i = \sum_{j=1}^n A_{ji}\alpha_j, \quad 1 \le i \le n.$$

These equations may be written in the equivalent form

$$\sum_{i=1}^{n} (\delta_{ij}T - A_{ji}I)\alpha_j = 0, \qquad 1 \le i \le n.$$

Let B denote the element of $K^{n \times n}$ with entries

$$B_{ij} = \delta_{ij}T - A_{ji}I.$$

When n = 2

$$B = \begin{bmatrix} T - A_{11}I & -A_{21}I \\ -A_{12}I & T - A_{22}I \end{bmatrix}$$

and

$$\det B = (T - A_{11}I)(T - A_{22}I) - A_{12}A_{21}I = T^2 - (A_{11} + A_{22})T + (A_{11}A_{22} - A_{12}A_{21})I = f(T)$$

where f is the characteristic polynomial:

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

 $f = x^2 - (\operatorname{trace} A)x + \det A.$

For the case n > 2, it is also clear that

 $\det B = f(T)$

since f is the determinant of the matrix xI - A whose entries are the polynomials

$$(xI - A)_{ij} = \delta_{ij}x - A_{ji}.$$

We wish to show that f(T) = 0. In order that f(T) be the zero operator, it is necessary and sufficient that $(\det B)\alpha_k = 0$ for $k = 1, \ldots, n$. By the definition of B, the vectors $\alpha_1, \ldots, \alpha_n$ satisfy the equations

(6-6)
$$\sum_{j=1}^{n} B_{ij} \alpha_j = 0, \quad 1 \le i \le n.$$

When n = 2, it is suggestive to write (6-6) in the form

$$\begin{bmatrix} T - A_{11}I & -A_{21}I \\ -A_{12}I & T - A_{22}I \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

In this case, the classical adjoint, adj B is the matrix

$$\tilde{B} = \begin{bmatrix} T - A_{22}I & A_{21}I \\ A_{12}I & T - A_{11}I \end{bmatrix}$$

and

$$\tilde{B}B = \begin{bmatrix} \det B & 0 \\ 0 & \det B \end{bmatrix}.$$

Hence, we have

$$(\det B) \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix} = (\tilde{B}B) \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix}$$
$$= \tilde{B} \left(B \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix} \right)$$
$$= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \cdot$$

In the general case, let $\tilde{B} = \operatorname{adj} B$. Then by (6-6)

$$\sum_{j=1}^{n} \tilde{B}_{ki} B_{ij} \alpha_j = 0$$

for each pair k, i, and summing on i, we have

$$0 = \sum_{i=1}^{n} \sum_{j=1}^{n} \widetilde{B}_{ki} B_{ij} \alpha_j$$
$$= \sum_{j=1}^{n} \left(\sum_{i=1}^{n} \widetilde{B}_{ki} B_{ij} \right) \alpha_j.$$

Now $\tilde{B}B = (\det B)I$, so that

$$\sum_{i=1}^n \tilde{B}_{ki} B_{ij} = \delta_{kj} \det B.$$

Therefore

$$0 = \sum_{j=1}^{n} \delta_{kj} (\det B) \alpha_j$$

= $(\det B) \alpha_k$, $1 \le k \le n$.

The Cayley-Hamilton theorem is useful to us at this point primarily because it narrows down the search for the minimal polynomials of various operators. If we know the matrix A which represents T in some ordered basis, then we can compute the characteristic polynomial f. We know that the minimal polynomial p divides f and that the two polynomials have the same roots. There is no method for computing precisely the roots of a polynomial (unless its degree is small); however, if f factors

(6-7)
$$f = (x - c_1)^{d_1} \cdots (x - c_k)^{d_k}, \quad c_1, \ldots, c_k \text{ distinct, } d_i \ge 1$$

then

(6-8)
$$p = (x - c_1)^{r_1} \cdots (x - c_k)^{r_k}, \quad 1 \le r_j \le d_j.$$

That is all we can say in general. If f is the polynomial (6-7) and has degree n, then for every polynomial p as in (6-8) we can find an $n \times n$ matrix which has f as its characteristic polynomial and p as its minimal

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

polynomial. We shall not prove this now. But, we want to emphasize the fact that the knowledge that the characteristic polynomial has the form (6-7) tells us that the minimal polynomial has the form (6-8), and it tells us nothing else about p.

EXAMPLE 5. Let A be the 4×4 (rational) matrix

		Γ0	1	0	17	
A =	1	0	1	0		
	0	1	0	1		
	1	0	1	0		

The powers of A are easy to compute:

$$A^{2} = \begin{bmatrix} 2 & 0 & 2 & 0 \\ 0 & 2 & 0 & 2 \\ 2 & 0 & 2 & 0 \\ 0 & 2 & 0 & 2 \end{bmatrix}$$
$$A^{3} = \begin{bmatrix} 0 & 4 & 0 & 4 \\ 4 & 0 & 4 & 0 \\ 0 & 4 & 0 & 4 \\ 4 & 0 & 4 & 0 \end{bmatrix}.$$

Thus $A^3 = 4A$, i.e., if $p = x^3 - 4x = x(x + 2)(x - 2)$, then p(A) = 0. The minimal polynomial for A must divide p. That minimal polynomial is obviously not of degree 1, since that would mean that A was a scalar multiple of the identity. Hence, the candidates for the minimal polynomial are: $p, x(x + 2), x(x - 2), x^2 - 4$. The three quadratic polynomials can be eliminated because it is obvious at a glance that $A^2 \neq -2A$, $A^2 \neq 2A$, $A^2 \neq 4I$. Therefore p is the minimal polynomial for A. In particular 0, 2, and -2 are the characteristic values of A. One of the factors x, x - 2, x + 2 must be repeated twice in the characteristic polynomial. Evidently, rank (A) = 2. Consequently there is a two-dimensional space of characteristic vectors associated with the characteristic value 0. From Theorem 2, it should now be clear that the characteristic polynomial is $x^2(x^2 - 4)$ and that A is similar over the field of rational numbers to the matrix

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

Invariant Subspaces

Definition. Let V be a vector space and T a linear operator on V. If W is a subspace of V, we say that W is **invariant under** T if for each vector α in W the vector T α is in W, i.e., if T(W) is contained in W.

EXAMPLE 6. If T is any linear operator on V, then V is invariant under T, as is the zero subspace. The range of T and the null space of T are also invariant under T.

EXAMPLE 7. Let F be a field and let D be the differentiation operator on the space F[x] of polynomials over F. Let n be a positive integer and let W be the subspace of polynomials of degree not greater than n. Then Wis invariant under D. This is just another way of saying that D is 'degree decreasing.'

space V. Let W be the subspace spanned by all of the characteristic vectors EXAMPLE Let T be any linear operator on a finite-dimensional

space V. Let W be the subspace spanned by all of the characteristic vectors

of T. Let c_1, \ldots, c_k be the distinct characteristic values of T. For each i, let W_i be the space of characteristic vectors associated with the characteristic value c_i , and let \mathfrak{B}_i be an ordered basis for W_i . The lemma before Theorem 2 tells us that $\mathfrak{B}' = (\mathfrak{B}_1, \ldots, \mathfrak{B}_k)$ is an ordered basis for W. In particular,

 $\dim W = \dim W_1 + \cdots + \dim W_k.$

Let $\mathfrak{B}' = \{\alpha_1, \ldots, \alpha_r\}$ so that the first few α 's form the basis \mathfrak{B}_1 , the next few \mathfrak{B}_2 , and so on. Then

$$T\alpha_i = t_i\alpha_i, \qquad i = 1, \ldots, r$$

where $(t_1, \ldots, t_r) = (c_1, c_1, \ldots, c_1, \ldots, c_k, c_k, \ldots, c_k)$ with c_i repeated dim W_i times.

Now W is invariant under T, since for each α in W we have

$$\alpha = x_1\alpha_1 + \cdots + x_r\alpha_r$$
$$T\alpha = t_1x_1\alpha_1 + \cdots + t_rx_r\alpha_r.$$

Choose any other vectors $\alpha_{r+1}, \ldots, \alpha_n$ in V such that $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ is a basis for V. The matrix of T relative to \mathfrak{B} has the block form (6-10), and the matrix of the restriction operator T_W relative to the basis \mathfrak{B}' is

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

$$B = \begin{bmatrix} t_1 & 0 & \cdots & 0 \\ 0 & t_2 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & t_r \end{bmatrix}$$

The characteristic polynomial of B (i.e., of T_W) is

 $g = (x - c_1)^{e_1} \cdots (x - c_k)^{e_k}$

where $e_i = \dim W_i$. Furthermore, g divides f, the characteristic polynomial for T. Therefore, the multiplicity of c_i as a root of f is at least dim W_i .

All of this should make Theorem 2 transparent. It merely says that T is diagonalizable if and only if r = n, if and only if $e_1 + \cdots + e_k = n$. It does not help us too much with the non-diagonalizable case, since we don't know the matrices C and D of (6-10).

Definition. Let W be an invariant subspace for T and let α be a vector in V. The T-conductor of α into W is the set $S_T(\alpha; W)$, which consists of all polynomials g (over the scalar field) such that $g(T)\alpha$ is in W.

Since the operator T will be fixed throughout most discussions, we shall usually drop the subscript T and write $S(\alpha; W)$. The authors usually call that collection of polynomials the 'stuffer' (das einstopfende Ideal). 'Conductor' is the more standard term, preferred by those who envision a less aggressive operator g(T), gently leading the vector α into W. In the special case $W = \{0\}$ the conductor is called the *T*-annihilator of α .

Lemma. If W is an invariant subspace for T, then W is invariant under every polynomial in T. Thus, for each α in V, the conductor $S(\alpha; W)$ is an ideal in the polynomial algebra F[x].

Proof. If β is in W, then $T\beta$ is in W. Consequently, $T(T\beta) = T^2\beta$ is in W. By induction, $T^k\beta$ is in W for each k. Take linear combinations to see that $f(T)\beta$ is in W for every polynomial f.

The definition of $S(\alpha; W)$ makes sense if W is any subset of V. If W is a subspace, then $S(\alpha; W)$ is a subspace of F[x], because

$$(cf+g)(T) = cf(T) + g(T).$$

If W is also invariant under T, let g be a polynomial in $S(\alpha; W)$, i.e., let $g(T)\alpha$ be in W. If f is any polynomial, then $f(T)[g(T)\alpha]$ will be in W. Since

$$(fg)(T) = f(T)g(T)$$

fg is in $S(\alpha; W)$. Thus the conductor absorbs multiplication by any polynomial.

KARPAGAM ACADEMY OF HIGHER EDUCATION CLASS: II B.Sc MATHEMATICS COURSE NAME: Ring Theory and Linear Algebra II COURSE CODE: 16MMU403 UNIT: III BATCH-2016-2019

The unique monic generator of the ideal $S(\alpha; W)$ is also called the *T*-conductor of α into *W* (the *T*-annihilator in case $W = \{0\}$). The *T*-conductor of α into *W* is the monic polynomial *g* of least degree such that $g(T)\alpha$ is in *W*. A polynomial *f* is in $S(\alpha; W)$ if and only if *g* divides *f*. Note that the conductor $S(\alpha; W)$ always contains the minimal polynomial for *T*; hence, every *T*-conductor divides the minimal polynomial for *T*.

As the first illustration of how to use the conductor $S(\alpha; W)$, we shall characterize triangulable operators. The linear operator T is called **triangulable** if there is an ordered basis in which T is represented by a triangular matrix.

Lemma. Let V be a finite-dimensional vector space over the field F. Let T be a linear operator on V such that the minimal polynomial for T is a product of linear factors

$$p = (x - c_1)^{r_1} \cdots (x - c_k)^{r_k}, \quad c_i \text{ in } F.$$

Let W be a proper (W \neq V) subspace of V which is invariant under T. There exists a vector α in V such that

(a) α is not in W;

(b) $(\mathbf{T} - \mathbf{cI})\alpha$ is in W, for some characteristic value c of the operator T.

Proof. What (a) and (b) say is that the *T*-conductor of α into *W* is a linear polynomial. Let β be any vector in *V* which is not in *W*. Let *g* be the *T*-conductor of β into *W*. Then *g* divides *p*, the minimal polynomial for *T*. Since β is not in *W*, the polynomial *g* is not constant. Therefore,

$$g = (x - c_1)^{e_1} \cdots (x - c_k)^{e_k}$$

where at least one of the integers e_i is positive. Choose j so that $e_j > 0$. Then $(x - c_j)$ divides g:

$$g = (x - c_j)h.$$

By the definition of g, the vector $\alpha = h(T)\beta$ cannot be in W. But

$$(T - c_j I) \alpha = (T - c_j I) h(T) \beta$$

= $g(T) \beta$

is in W.

Theorem Let V be a finite-dimensional vector space over the field F

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

and let T be a linear operator on V. Then T is triangulable if and only if the minimal polynomial for T is a product of linear polynomials over F.

Proof. Suppose that the minimal polynomial factors

$$p = (x - c_1)^{r_1} \cdots (x - c_k)^{r_k}.$$

By repeated application of the lemma above, we shall arrive at an ordered basis $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ in which the matrix representing T is upper-triangular:

(6-11)
$$[T]_{\mathfrak{B}} = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \cdots & a_{1n} \\ 0 & a_{22} & a_{23} & \cdots & a_{2n} \\ 0 & 0 & a_{33} & \cdots & a_{3n} \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & 0 & \cdots & a_{nn} \end{bmatrix}.$$

Now (6-11) merely says that

(6-12) $T\alpha_j = a_{1j}\alpha_1 + \cdots + a_{jj}\alpha_j, \quad 1 \le j \le n$ that is, $T\alpha_j$ is in the subspace spanned by $\alpha_1, \ldots, \alpha_j$. To find $\alpha_1, \ldots, \alpha_n$, we start by applying the lemma to the subspace $W = \{0\}$, to obtain the vector α_1 . Then apply the lemma to W_1 , the space spanned by α_1 , and we

obtain α_2 . Next apply the lemma to W_2 , the space spanned by α_1 and α_2 . Continue in that way. One point deserves comment. After $\alpha_1, \ldots, \alpha_i$ have been found, it is the triangular-type relations (6-12) for $j = 1, \ldots, i$ which ensure that the subspace spanned by $\alpha_1, \ldots, \alpha_i$ is invariant under T.

If T is triangulable, it is evident that the characteristic polynomial for T has the form

$$f = (x - c_1)^{d_1} \cdots (x - c_k)^{d_k}, \qquad c_i \text{ in } F.$$

Just look at the triangular matrix (6-11). The diagonal entries a_{11}, \ldots, a_{1n} are the characteristic values, with c_i repeated d_i times. But, if f can be so factored, so can the minimal polynomial p, because it divides f.

Corollary. Let F be an algebraically closed field, e.g., the complex number field. Every $n \times n$ matrix over F is similar over F to a triangular matrix. **Theorem** Let V be a finite-dimensional vector space over the field F

CLASS: II B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra IICOURSE CODE: 16MMU403UNIT: IIIBATCH-2016-2019

and let T be a linear operator on V. Then T is diagonalizable if and only if the minimal polynomial for T has the form

$$\mathbf{p} = (\mathbf{x} - \mathbf{c}_1) \cdots (\mathbf{x} - \mathbf{c}_k)$$

where c_1, \ldots, c_k are distinct elements of F.

Proof. We have noted earlier that, if T is diagonalizable, its minimal polynomial is a product of distinct linear factors (see the discussion prior to Example 4). To prove the converse, let W be the subspace spanned by all of the characteristic vectors of T, and suppose $W \neq V$. By the lemma used in the proof of Theorem 5, there is a vector α not in W and a characteristic value c_i of T such that the vector

$$\beta = (T - c_j I)\alpha$$

lies in W. Since β is in W,

 $\beta = \beta_1 + \cdots + \beta_k$

where $T\beta_i = c_i\beta_i$, $1 \leq i \leq k$, and therefore the vector

 $h(T)\beta = h(c_1)\beta_1 + \cdots + h(c_k)\beta_k$

is in W, for every polynomial h.

Now $p = (x - c_i)q$, for some polynomial q. Also

$$q - q(c_j) = (x - c_j)h.$$

We have

$$q(T)\alpha - q(c_j)\alpha = h(T)(T - c_j I)\alpha = h(T)\beta$$

But $h(T)\beta$ is in W and, since

$$0 = p(T)\alpha = (T - c_i I)q(T)\alpha$$

the vector $q(T)\alpha$ is in W. Therefore, $q(c_j)\alpha$ is in W. Since α is not in W, we have $q(c_j) = 0$. That contradicts the fact that p has distinct roots.

INNER PRODUCT SPACES

Inner product spaces and norms - Gram-Schmidt orthogonalisation process - Orthogonal complements - Bessel's inequality - The adjoint of a linear operator.

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

Inner Product Spaces

Definition. Let F be the field of real numbers or the field of complex numbers, and V a vector space over F. An **inner product** on V is a function which assigns to each ordered pair of vectors α , β in V a scalar ($\alpha|\beta$) in F in such a way that for all α , β , γ in V and all scalars c

- (a) $(\alpha + \beta | \gamma) = (\alpha | \gamma) + (\beta | \gamma);$
- (b) $(c\alpha|\beta) = c(\alpha|\beta);$
- (c) $(\beta | \alpha) = (\overline{\alpha | \beta})$, the bar denoting complex conjugation;
- (d) $(\alpha | \alpha) > 0$ if $\alpha \neq 0$.

It should be observed that conditions (a), (b), and (c) imply that

(e)
$$(\alpha | c\beta + \gamma) = \bar{c}(\alpha | \beta) + (\alpha | \gamma).$$

One other point should be made. When F is the field R of real numbers, the complex conjugates appearing in (c) and (e) are superfluous; however, in the complex case they are necessary for the consistency of the conditions. Without these complex conjugates, we would have the contradiction:

 $(\alpha | \alpha) > 0$ and $(i\alpha | i\alpha) = -1(\alpha | \alpha) > 0.$

In the examples that follow and throughout the chapter, F is either the field of real numbers or the field of complex numbers.

EXAMPLE On F^n there is an inner product which we call the standard inner product. It is defined on $\alpha = (x_1, \ldots, x_n)$ and $\beta = (y_1, \ldots, y_n)$ by

(8-1)
$$(\alpha|\beta) = \sum_{j} x_{j} \bar{y}_{j}.$$

When F = R, this may also be written

$$(\alpha|\beta) = \sum_{j} x_{j} y_{j}.$$

In the real case, the standard inner product is often called the dot or scalar product and denoted by $\alpha \cdot \beta$.

EXAMPLE For $\alpha = (x_1, x_2)$ and $\beta = (y_1, y_2)$ in \mathbb{R}^2 , let

KARPAGAM ACADEMY OF HIGHER EDUCATIONCLASS: III B.Sc MATHEMATICS
COURSE CODE: 17MMU601ACOURSE NAME: Ring Theory and Linear Algebra-II
UNIT: IV $(\alpha|\beta) = x_1y_1 - x_2y_1 - x_1y_2 + 4x_2y_2.$

Since $(\alpha | \alpha) = (x_1 - x_2)^2 + 3x_2^2$, it follows that $(\alpha | \alpha) > 0$ if $\alpha \neq 0$. Conditions (a), (b), and (c) of the definition are easily verified.

EXAMPLE 3. Let V be $F^{n \times n}$, the space of all $n \times n$ matrices over F. Then V is isomorphic to F^{n^2} in a natural way. It therefore follows from Example 1 that the equation

$$(A|B) = \sum_{j,k} A_{jk} \overline{B}_{jk}$$

defines an inner product on V. Furthermore, if we introduce the **conjugate transpose** matrix B^* , where $B_{kj}^* = \overline{B}_{jk}$, we may express this inner product on $F^{n \times n}$ in terms of the trace function:

$$(A|B) = tr (AB^*) = tr (B^*A).$$

For

$$\operatorname{tr} (AB^*) = \sum_{j} (AB^*)_{jj}$$
$$= \sum_{j} \sum_{k} A_{jk} B^*_{kj}$$
$$= \sum_{j} \sum_{k} A_{jk} \overline{B}_{jk}.$$

EXAMPLE Let $F^{n\times 1}$ be the space of $n \times 1$ (column) matrices over F, and let Q be an $n \times n$ invertible matrix over F. For X, Y in $F^{n\times 1}$ set

$$(X|Y) = Y^*Q^*QX.$$

We are identifying the 1×1 matrix on the right with its single entry. When Q is the identity matrix, this inner product is essentially the same as that in Example 1; we call it the **standard inner product** on $F^{n\times 1}$. The reader should note that the terminology 'standard inner product' is used in two special contexts. For a general finite-dimensional vector space over F, there is no obvious inner product that one may call standard.

EXAMPLE 5. Let V be the vector space of all continuous complexvalued functions on the unit interval, $0 \le t \le 1$. Let

$$(f|g) = \int_0^1 f(t) \overline{g(t)} dt.$$

The reader is probably more familiar with the space of real-valued continuous functions on the unit interval, and for this space the complex conjugate on g may be omitted.

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

Inner Product Spaces

Definition. An inner product space is a real or complex vector space, together with a specified inner product on that space.

A finite-dimensional real inner product space is often called a Euclidean space. A complex inner product space is often referred to as a unitary space.

Theorem

If V is an inner product space, then for any vectors α , β in V and any scalar c

(i) $||c\alpha|| = |c| ||\alpha||;$

- (ii) $||\alpha|| > 0$ for $\alpha \neq 0$;
- (iii) $|(\alpha|\beta)| \leq ||\alpha|| ||\beta||;$
- (iv) $||\alpha + \beta|| \le ||\alpha|| + ||\beta||$.

Proof. Statements (i) and (ii) follow almost immediately from the various definitions involved. The inequality in (iii) is clearly valid when $\alpha = 0$. If $\alpha \neq 0$, put

$$\gamma = \beta - \frac{(\beta | \alpha)}{||\alpha||^2} \alpha.$$

Then $(\gamma | \alpha) = 0$ and

$$0 \leq ||\gamma||^{2} = \left(\beta - \frac{(\beta|\alpha)}{||\alpha||^{2}} \alpha \left|\beta - \frac{(\beta|\alpha)}{||\alpha||^{2}} \alpha\right)$$
$$= (\beta|\beta) - \frac{(\beta|\alpha)(\alpha|\beta)}{||\alpha||^{2}}$$
$$= ||\beta||^{2} - \frac{|(\alpha|\beta)|^{2}}{||\alpha||^{2}}.$$
Hence $|(\alpha|\beta)|^{2} \leq ||\alpha||^{2}||\beta||^{2}$. Now using (c) we find that
 $||\alpha + \beta||^{2} = ||\alpha||^{2} + (\alpha|\beta) + (\beta|\alpha) + ||\beta||^{2}$
$$= ||\alpha||^{2} + 2 \operatorname{Re}(\alpha|\beta) + ||\beta||^{2}$$
$$\leq ||\alpha||^{2} + 2 ||\alpha|| ||\beta|| + ||\beta||^{2}$$
$$= (||\alpha|| + ||\beta||)^{2}.$$

Thus, $||\alpha + \beta|| \le ||\alpha|| + ||\beta||$.

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

The inequality in (iii) is called the **Cauchy-Schwarz inequality**. It has a wide variety of applications. The proof shows that if (for example) α is non-zero, then $|(\alpha|\beta)| < ||\alpha|| ||\beta||$ unless

$$\beta = \frac{(\beta|\alpha)}{||\alpha||^2} \alpha.$$

Thus, equality occurs in (iii) if and only if α and β are linearly dependent.

Example

inner products given in Examples 1, 2, 3, and 5, we obtain the following:

(a)
$$|\Sigma x_k \bar{y}_k| \leq (\Sigma |x_k|^2)^{1/2} (\Sigma |y_k|^2)^{1/2}$$

(b)
$$|x_1y_1 - x_2y_1 - x_1y_2 + 4x_2y_2|$$

$$\leq ((x_1 - x_2)^2 + 3x_2^2)^{1/2}((y_1 - y_2)^2 + 3y_2^2)^{1/2}$$

(c)
$$|\operatorname{tr} (AB^*)| \leq (\operatorname{tr} (AA^*))^{1/2} (\operatorname{tr} (BB^*))^{1/2}$$

(d) $\left| \int_0^1 f(x)\overline{g(x)} \, dx \right| \leq \left(\int_0^1 |f(x)|^2 \, dx \right)^{1/2} \left(\int_0^1 |g(x)|^2 \, dx \right)^{1/2}$.

Definitions. Let α and β be vectors in an inner product space V. Then α is **orthogonal** to β if $(\alpha|\beta) = 0$; since this implies β is orthogonal to α , we often simply say that α and β are orthogonal. If S is a set of vectors in V, S is called an **orthogonal set** provided all pairs of distinct vectors in S are orthogonal. An **orthonormal set** is an orthogonal set S with the additional property that $||\alpha|| = 1$ for every α in S.

Example

The vector (x, y) in \mathbb{R}^2 is orthogonal to (-y, x) with respect to the standard inner product, for

$$((x, y)|(-y, x)) = -xy + yx = 0.$$

However, if R^2 is equipped with the inner product of Example 2, then (x, y) and (-y, x) are orthogonal if and only if

$$y = \frac{1}{2} \left(-3 \pm \sqrt{13} \right) x$$

Example

Let V be the space of continuous complex-valued (or

COURSE NAME: Ring Theory and Linear Algebra-II CLASS: III B.Sc MATHEMATICS COURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020real-valued) functions on the interval $0 \le x \le 1$ with the inner product

$$(f|g) = \int_0^1 f(x)\overline{g(x)} \, dx.$$

Suppose $f_n(x) = \sqrt{2} \cos 2\pi nx$ and that $g_n(x) = \sqrt{2} \sin 2\pi nx$. Then $\{1, f_1, g_1, f_2, g_2, \ldots\}$ is an infinite orthonormal set. In the complex case, we may also form the linear combinations

$$\frac{1}{\sqrt{2}}(f_n+ig_n), \qquad n=1,2,\ldots$$

In this way we get a new orthonormal set S which consists of all functions of the form

$$h_n(x) = e^{2\pi i n x}, \qquad n = \pm 1, \pm 2, \ldots$$

The set S' obtained from S by adjoining the constant function 1 is also orthonormal. We assume here that the reader is familiar with the calculation of the integrals in question.

Theorem

An orthogonal set of non-zero vectors is linearly independent.

Proof. Let S be a finite or infinite orthogonal set of non-zero vectors in a given inner product space. Suppose $\alpha_1, \alpha_2, \ldots, \alpha_m$ are distinct vectors in S and that

$$\beta = c_1\alpha_1 + c_2\alpha_2 + \cdots + c_m\alpha_m.$$

Then

$$\begin{aligned} (\beta | \alpha_k) &= \left(\sum_j c_j \alpha_j | \alpha_k \right) \\ &= \sum_j c_j (\alpha_j | \alpha_k) \\ &= c_k (\alpha_k | \alpha_k). \end{aligned}$$

Since $(\alpha_k | \alpha_k) \neq 0$, it follows that

$$c_k = rac{(eta|lpha_k)}{||lpha_k||^2}, \quad 1 \le k \le m.$$

Thus when $\beta = 0$, each $c_k = 0$; so S is an independent set.

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

Corollary. If a vector β is a linear combination of an orthogonal sequence of non-zero vectors $\alpha_1, \ldots, \alpha_m$, then β is the particular linear combination

(8-8)
$$\beta = \sum_{k=1}^{m} \frac{(\beta | \alpha_k)}{||\alpha_k||^2} \alpha_k.$$

This corollary follows from the proof of the theorem. There is another corollary which although obvious, should be mentioned. If $\{\alpha_1, \ldots, \alpha_m\}$ is an orthogonal set of non-zero vectors in a finite-dimensional inner product space V, then $m \leq \dim V$. This says that the number of mutually orthogonal directions in V cannot exceed the algebraically defined dimension of V. The maximum number of mutually orthogonal directions in Vis what one would intuitively regard as the geometric dimension of V, and we have just seen that this is not greater than the algebraic dimension. The fact that these two dimensions are equal is a particular corollary of the next result.

Theorem

Let V be an inner product space and let β_1, \ldots, β_n be any independent vectors in V. Then one may construct orthogonal vectors $\alpha_1, \ldots, \alpha_n$ in V such that for each $k = 1, 2, \ldots$, n the set

$$\{\alpha_1,\ldots,\alpha_k\}$$

is a basis for the subspace spanned by β_1, \ldots, β_k .

Proof. The vectors $\alpha_1, \ldots, \alpha_n$ will be obtained by means of a construction known as the **Gram-Schmidt orthogonalization process.** First let $\alpha_1 = \beta_1$. The other vectors are then given inductively as follows: Suppose $\alpha_1, \ldots, \alpha_m$ $(1 \le m < n)$ have been chosen so that for every k

$$\{\alpha_1,\ldots,\alpha_k\}, \quad 1\leq k\leq m$$

is an orthogonal basis for the subspace of V that is spanned by β_1, \ldots, β_k . To construct the next vector α_{m+1} , let

(8-9)
$$\alpha_{m+1} = \beta_{m+1} - \sum_{k=1}^{m} \frac{(\beta_{m+1}|\alpha_k)}{||\alpha_k||^2} \alpha_k.$$

Then $\alpha_{m+1} \neq 0$. For otherwise β_{m+1} is a linear combination of $\alpha_1, \ldots, \alpha_m$ and hence a linear combination of β_1, \ldots, β_m . Furthermore, if $1 \leq j \leq m$, then

$$\begin{aligned} (\alpha_{m+1}|\alpha_j) \ &= \ (\beta_{m+1}|\alpha_j) \ - \ \sum_{k=1}^m \frac{(\beta_{m+1}|\alpha_k)}{||\alpha_k||^2} \ (\alpha_k|\alpha_j) \\ &= \ (\beta_{m+1}|\alpha_j) \ - \ (\beta_{m+1}|\alpha_j) \\ &= \ 0. \end{aligned}$$

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

Therefore $\{\alpha_1, \ldots, \alpha_{m+1}\}$ is an orthogonal set consisting of m + 1 nonzero vectors in the subspace spanned by $\beta_1, \ldots, \beta_{m+1}$. By Theorem 2, it is a basis for this subspace. Thus the vectors $\alpha_1, \ldots, \alpha_n$ may be constructed one after the other in accordance with (8-9). In particular, when n = 4, we have

(8-10)

$$\alpha_{1} = \beta_{1}$$

$$\alpha_{2} = \beta_{2} - \frac{(\beta_{2}|\alpha_{1})}{||\alpha_{1}||^{2}} \alpha_{1}$$

$$\alpha_{3} = \beta_{3} - \frac{(\beta_{3}|\alpha_{1})}{||\alpha_{1}||^{2}} \alpha_{1} - \frac{(\beta_{3}|\alpha_{2})}{||\alpha_{2}||^{2}} \alpha_{2}$$

$$\alpha_{4} = \beta_{4} - \frac{(\beta_{4}|\alpha_{1})}{||\alpha_{1}||^{2}} \alpha_{1} - \frac{(\beta_{4}|\alpha_{2})}{||\alpha_{2}||^{2}} \alpha_{2} - \frac{(\beta_{4}|\alpha_{3})}{||\alpha_{3}||^{2}} \alpha_{3}.$$

Corollary. Every finite-dimensional inner product space has an orthonormal basis.

Proof. Let V be a finite-dimensional inner product space and $\{\beta_1, \ldots, \beta_n\}$ a basis for V. Apply the Gram-Schmidt process to construct an orthogonal basis $\{\alpha_1, \ldots, \alpha_n\}$. Then to obtain an orthonormal basis, simply replace each vector α_k by $\alpha_k/||\alpha_k||$.

Example

Consider the vectors

$$\beta_1 = (3, 0, 4)$$

 $\beta_2 = (-1, 0, 7)$
 $\beta_3 = (2, 9, 11)$

in R^3 equipped with the standard inner product. Applying the Gram-Schmidt process to β_1 , β_2 , β_3 , we obtain the following vectors.

$$\begin{aligned} \alpha_1 &= (3, 0, 4) \\ \alpha_2 &= (-1, 0, 7) - \frac{((-1, 0, 7)|(3, 0, 4))}{25} (3, 0, 4) \\ &= (-1, 0, 7) - (3, 0, 4) \\ &= (-4, 0, 3) \\ \alpha_3 &= (2, 9, 11) - \frac{((2, 9, 11)|(3, 0, 4))}{25} (3, 0, 4) \\ &- \frac{((2, 9, 11)|(-4, 0, 3))}{25} (-4, 0, 3) \\ &= (2, 9, 11) - 2(3, 0, 4) - -4, 0, 3) \\ &= (0, 9, 0). \end{aligned}$$

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

These vectors are evidently non-zero and mutually orthogonal. Hence $\{\alpha_1, \alpha_2, \alpha_3\}$ is an orthogonal basis for R^3 . To express an arbitrary vector (x_1, x_2, x_3) in R^3 as a linear combination of $\alpha_1, \alpha_2, \alpha_3$ it is *not* necessary to solve any linear equations. For it suffices to use (8-8). Thus

$$(x_1, x_2, x_3) = \frac{3x_1 + 4x_3}{25} \alpha_1 + \frac{-4x_1 + 3x_3}{25} \alpha_2 + \frac{x_2}{9} \alpha_3$$

as is readily verified. In particular,

$$(1, 2, 3) = \frac{3}{5}(3, 0, 4) + \frac{1}{5}(-4, 0, 3) + \frac{2}{9}(0, 9, 0).$$

To put this point in another way, what we have shown is the following: The basis $\{f_1, f_2, f_3\}$ of $(\mathbb{R}^3)^*$ which is dual to the basis $\{\alpha_1, \alpha_2, \alpha_3\}$ is defined explicitly by the equations

$$f_1(x_1, x_2, x_3) = \frac{3x_1 + 4x_3}{25}$$
$$f_2(x_1, x_2, x_3) = \frac{-4x_1 + 3x_3}{25}$$

$$f_3(x_1, x_2, x_3) = \frac{x_2}{9}$$

and these equations may be written more generally in the form

$$f_j(x_1, x_2, x_3) = \frac{((x_1, x_2, x_3)|\alpha_j)}{||\alpha_j||^2}$$

Finally, note that from α_1 , α_2 , α_3 we get the orthonormal basis

$$\frac{1}{5}(3, 0, 4), \frac{1}{5}(-4, 0, 3), (0, 1, 0).$$

Example

Let
$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$
 where $a, b, c, and d$ are complex num-

CLASS: III B.Sc MATHEMATICS	COURSE NAME: Ring	Theory and Linear Algebra-II
COURSE CODE: 17MMU601A	UNIT: IV	BATCH-2017-2020
bers Set $\beta_1 = (a, b)$, $\beta_2 = (c, d)$.	and suppose that β_1	$\neq 0$. If we apply

the orthogonalization process to β_1 , β_2 , using the standard inner product in C^2 , we obtain the following vectors:

$$\begin{aligned} \alpha_1 &= (a, b) \\ \alpha_2 &= (c, d) - \frac{((c, d)|(a, b))}{|a|^2 + |b|^2} (a, b) \\ &= (c, d) - \frac{(c\bar{a} + d\bar{b})}{|a|^2 + |b|^2} (a, b) \\ &= \left(\frac{cb\bar{b} - d\bar{b}a}{|a|^2 + |b|^2}, \frac{d\bar{a}a - c\bar{a}b}{|a|^2 + |b|^2}\right) \\ &= \frac{\det A}{|a|^2 + |b|^2} (-\bar{b}, \bar{a}). \end{aligned}$$

Now the general theory tells us that $\alpha_2 \neq 0$ if and only if β_1 , β_2 are linearly independent. On the other hand, the formula for α_2 shows that this is the case if and only if det $A \neq 0$.

Theorem

Let W be a subspace of an inner product space V and let β be a vector in V.

(i) The vector α in W is a best approximation to β by vectors in W if and only if $\beta - \alpha$ is orthogonal to every vector in W.

(ii) If a best approximation to β by vectors in W exists, it is unique.

(iii) If W is finite-dimensional and $\{\alpha_1, \ldots, \alpha_n\}$ is any orthonormal basis for W, then the vector

$$lpha = \sum_{k} rac{(eta | lpha_{k})}{|| lpha_{k} ||^{2}} \, lpha_{k}$$

is the (unique) best approximation to β by vectors in W.

Proof. First note that if γ is any vector in V, then $\beta - \gamma = (\beta - \alpha) + (\alpha - \gamma)$, and

$$||\beta - \gamma||^2 = ||\beta - \alpha||^2 + 2 \operatorname{Re} (\beta - \alpha |\alpha - \gamma) + ||\alpha - \gamma||^2.$$

Now suppose $\beta - \alpha$ is orthogonal to every vector in W, that γ is in W and that $\gamma \neq \alpha$. Then, since $\alpha - \gamma$ is in W, it follows that

$$\frac{||\beta - \gamma||^2}{||\beta - \alpha||^2} + \frac{||\alpha - \gamma||^2}{||\beta - \alpha||^2}.$$

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

Conversely, suppose that $||\beta - \gamma|| \ge ||\beta - \alpha||$ for every γ in W. Then from the first equation above it follows that

$$2 \operatorname{Re} \left(\beta - \alpha |\alpha - \gamma\right) + ||\alpha - \gamma||^2 \ge 0$$

for all γ in W. Since every vector in W may be expressed in the form $\alpha - \gamma$ with γ in W, we see that

$$2 \operatorname{Re} \left(\beta - \alpha | \tau\right) + ||\tau||^2 \ge 0$$

for every τ in W. In particular, if γ is in W and $\gamma \neq \alpha$, we may take

$$\tau = -\frac{(\beta - \alpha | \alpha - \gamma)}{||\alpha - \gamma||^2} (\alpha - \gamma).$$

Then the inequality reduces to the statement

$$-2 \frac{|(\beta - \alpha |\alpha - \gamma)|^2}{||\alpha - \gamma||^2} + \frac{|(\beta - \alpha |\alpha - \gamma)|^2}{||\alpha - \gamma||^2} \ge 0.$$

This holds if and only if $(\beta - \alpha | \alpha - \gamma) = 0$. Therefore, $\beta - \alpha$ is orthogonal to every vector in W. This completes the proof of the equivalence of the two conditions on α given in (i). The orthogonality condition is evidently satisfied by at most one vector in W, which proves (ii).

Now suppose that W is a finite-dimensional subspace of V. Then we know, as a corollary of Theorem 3, that W has an orthogonal basis. Let $\{\alpha_1, \ldots, \alpha_n\}$ be any orthogonal basis for W and define α by (8-11). Then, by the computation in the proof of Theorem 3, $\beta - \alpha$ is orthogonal to each of the vectors α_k ($\beta - \alpha$ is the vector obtained at the last stage when

the orthogonalization process is applied to $\alpha_1, \ldots, \alpha_n, \beta$). Thus $\beta - \alpha$ is orthogonal to every linear combination of $\alpha_1, \ldots, \alpha_n$, i.e., to every vector in W. If γ is in W and $\gamma \neq \alpha$, it follows that $||\beta - \gamma|| > ||\beta - \alpha||$. Therefore, α is the best approximation to β that lies in W.

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

Definition. Let V be an inner product space and S any set of vectors in V. The **orthogonal complement** of S is the set S^{\perp} of all vectors in V which are orthogonal to every vector in S.

The orthogonal complement of V is the zero subspace, and conversely $\{0\}^{\perp} = V$. If S is any subset of V, its orthogonal complement S^{\perp} (S perp) is always a subspace of V. For S is non-empty, since it contains 0; and whenever α and β are in S^{\perp} and c is any scalar,

$$(c\alpha + \beta|\gamma) = c(\alpha|\gamma) + (\beta|\gamma)$$
$$= c0 + 0$$
$$= 0$$

for every γ in S, thus $c\alpha + \beta$ also lies in S. In Theorem 4 the characteristic property of the vector α is that it is the only vector in W such that $\beta - \alpha$ belongs to W^{\perp} .

Definition. Whenever the vector α in Theorem 4 exists it is called the **orthogonal projection of** β on W. If every vector in V has an orthogonal projection on W, the mapping that assigns to each vector in V its orthogonal projection on W is called the **orthogonal projection of V on W**.

By Theorem 4, the orthogonal projection of an inner product space on a finite-dimensional subspace always exists. But Theorem 4 also implies the following result.

Corollary. Let V be an inner product space, W a finite-dimensional subspace, and E the orthogonal projection of V on W. Then the mapping

$$\beta \rightarrow \beta - E\beta$$

is the orthogonal projection of V on W^{\perp} .

Proof. Let β be an arbitrary vector in V. Then $\beta - E\beta$ is in W^{\perp} , and for any γ in W^{\perp} , $\beta - \gamma = E\beta + (\beta - E\beta - \gamma)$. Since $E\beta$ is in W and $\beta - E\beta - \gamma$ is in W^{\perp} , it follows that

$$\begin{aligned} ||\beta - \gamma||^2 &= ||E\beta||^2 + ||\beta - E\beta - \gamma||^2 \\ &\geq ||\beta - (\beta - E\beta)||^2 \end{aligned}$$

with strict inequality when $\gamma \neq \beta - E\beta$. Therefore, $\beta - E\beta$ is the best approximation to β by vectors in W^{\perp} .

Example

Give \mathbb{R}^3 the standard inner product. Then the orthogonal projection of (-10, 2, 8) on the subspace W that is spanned by

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

(3, 12, -1) is the vector

$$\begin{aligned} \alpha &= \frac{((-10,\,2,\,8)|(3,\,12,\,-1))}{9\,+\,144\,+\,1}\,(3,\,12,\,-1) \\ &= \frac{-14}{154}\,(3,\,12,\,-1). \end{aligned}$$

The orthogonal projection of R^3 on W is the linear transformation E defined by

$$(x_1, x_2, x_3) \rightarrow \left(\frac{3x_1 + 12x_2 - x_3}{154}\right) (3, 12, -1).$$

The rank of E is clearly 1; hence its nullity is 2. On the other hand,

$$E(x_1, x_2, x_3) = (0, 0, 0)$$

if and only if $3x_1 + 12x_2 - x_3 = 0$. This is the case if and only if (x_1, x_2, x_3) is in W^{\perp} . Therefore, W^{\perp} is the null space of E, and dim $(W^{\perp}) = 2$. Computing

$$(x_1, x_2, x_3) - \left(\frac{3x_1 + 12x_2 - x_3}{154}\right) (3, 12, -1)$$

we see that the orthogonal projection of R^3 on W^{\perp} is the linear transformation I - E that maps the vector (x_1, x_2, x_3) onto the vector

$$\frac{1}{154} (145x_1 - 36x_2 + 3x_3, -36x_1 + 10x_2 + 12x_3, 3x_1 + 12x_2 + 153x_3).$$

Theorem

Let W be a finite-dimensional subspace of an inner product space V and let E be the orthogonal projection of V on W. Then E is an idempotent linear transformation of V onto W, W^{\perp} is the null space of E, and

$$V = W \bigoplus W^{\perp}$$
.

Proof. Let β be an arbitrary vector in V. Then $E\beta$ is the best approximation to β that lies in W. In particular, $E\beta = \beta$ when β is in W. Therefore, $E(E\beta) = E\beta$ for every β in V; that is, E is idempotent: $E^2 = E$. To prove that E is a linear transformation, let α and β be any vectors in V and c an arbitrary scalar. Then, by Theorem 4, $\alpha - E\alpha$ and $\beta - E\beta$ are each orthogonal to every vector in W. Hence the vector

$$c(\alpha - E\alpha) + (\beta - E\beta) = (c\alpha + \beta) - (cE\alpha + E\beta)$$

also belongs to W^{\perp} . Since $cE\alpha + E\beta$ is a vector in W, it follows from Theorem 4 that

$$E(c\alpha + \beta) = cE\alpha + E\beta.$$

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

Of course, one may also prove the linearity of E by using (8-11). Again let β be any vector in V. Then $E\beta$ is the unique vector in W such that $\beta - E\beta$ is in W^{\perp} . Thus $E\beta = 0$ when β is in W^{\perp} . Conversely, β is in W^{\perp} when $E\beta = 0$. Thus W^{\perp} is the null space of E. The equation

$$\beta = E\beta + \beta - E\beta$$

shows that $V = W + W^{\perp}$; moreover, $W \cap W^{\perp} = \{0\}$. For if α is a vector in $W \cap W^{\perp}$, then $(\alpha | \alpha) = 0$. Therefore, $\alpha = 0$, and V is the direct sum of W and W^{\perp} .

Corollary. Under the conditions of the theorem, I - E is the orthogonal projection of V on W^{\perp} . It is an idempotent linear transformation of V onto W^{\perp} with null space W.

Proof. We have already seen that the mapping $\beta \rightarrow \beta - E\beta$ is the orthogonal projection of V on W^{\perp} . Since E is a linear transformation, this projection on W^{\perp} is the linear transformation I - E. From its geometric properties one sees that I - E is an idempotent transformation of V onto W. This also follows from the computation

$$(I - E)(I - E) = I - E - E + E^2$$

= $I - E$.

Moreover, $(I - E)\beta = 0$ if and only if $\beta = E\beta$, and this is the case if and only if β is in W. Therefore W is the null space of I - E.

The Gram-Schmidt process may now be described geometrically in the following way. Given an inner product space V and vectors β_1, \ldots, β_n in V, let P_k (k > 1) be the orthogonal projection of V on the orthogonal complement of the subspace spanned by $\beta_1, \ldots, \beta_{k-1}$, and set $P_1 = I$. Then the vectors one obtains by applying the orthogonalization process to β_1, \ldots, β_n are defined by the equations

(8-12)
$$\alpha_k = P_k \beta_k, \quad 1 \le k \le n.$$

Theorem 5 implies another result known as **Bessel's inequality**.

Corollary. Let $\{\alpha_1, \ldots, \alpha_n\}$ be an orthogonal set of non-zero vectors in an inner product space V. If β is any vector in V, then

$$\sum_{\mathbf{k}}rac{|(eta|lpha_{\mathbf{k}})|^2}{||lpha_{\mathbf{k}}||^2}\leq ||eta||^2$$

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

and equality holds if and only if

$$\beta = \sum_{k} \frac{(\beta |\alpha_{k})}{||\alpha_{k}||^{2}} \alpha_{k}.$$
Proof. Let $\gamma = \sum_{k} [(\beta |\alpha_{k})/||\alpha_{k}||^{2}] \alpha_{k}.$ Then $\beta = \gamma + \delta$ where $(\gamma |\delta) = 0.$ Hence
$$||\beta||^{2} = ||\gamma||^{2} + ||\delta||^{2}.$$

It now suffices to prove that

$$||\gamma||^2 = \sum_k \frac{|(\beta|\alpha_k)|^2}{||\alpha_k||^2}$$

This is straightforward computation in which one uses the fact that $(\alpha_j | \alpha_k) = 0$ for $j \neq k$.

In the special case in which $\{\alpha_1, \ldots, \alpha_n\}$ is an orthonormal set, Bessel's inequality says that

$$\sum_{k} |(\beta|\alpha_k)|^2 \le ||\beta||^2.$$

The corollary also tells us in this case that β is in the subspace spanned by $\alpha_1, \ldots, \alpha_n$ if and only if

$$\beta = \sum_{k} (\beta | \alpha_k) \alpha_k$$

or if and only if Bessel's inequality is actually an equality. Of course, in the event that V is finite dimensional and $\{\alpha_1, \ldots, \alpha_n\}$ is an orthogonal basis for V, the above formula holds for every vector β in V. In other words, if $\{\alpha_1, \ldots, \alpha_n\}$ is an orthonormal basis for V, the kth coordinate of β in the ordered basis $\{\alpha_1, \ldots, \alpha_n\}$ is $(\beta | \alpha_k)$.

Example

We shall apply the last corollary to the orthogonal sets described in Example 11. We find that

(a)
$$\sum_{k=-n}^{n} \left| \int_{0}^{1} f(t) e^{-2\pi i k t} dt \right|^{2} \leq \int_{0}^{1} |f(t)|^{2} dt$$

(b)
$$\int_0^1 \left| \sum_{k=-n}^n c_k e^{2\pi i k t} \right|^2 dt = \sum_{k=-n}^n |c_k|^2$$

(c)
$$\int_{0}^{1} (\sqrt{2} \cos 2\pi t + \sqrt{2} \sin 4\pi t)^{2} dt = 1 + 1 = 2.$$

Linear Functionals and Adjoints

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

Theorem

Let V be a finite-dimensional inner product space, and f a linear functional on V. Then there exists a unique vector β in V such that $f(\alpha) = (\alpha|\beta)$ for all α in V.

Proof. Let $\{\alpha_1, \alpha_2, \ldots, \alpha_n\}$ be an orthonormal basis for V. Put

(8-13)
$$\beta = \sum_{j=1}^{n} \overline{f(\alpha_j)} \alpha_j$$

and let f_{β} be the linear functional defined by

$$f_{\beta}(\alpha) = (\alpha|\beta).$$

Then

$$f_{\beta}(\alpha_k) = (\alpha_k | \sum_j \overline{f(\alpha_j)} \alpha_j) = f(\alpha_k).$$

Since this is true for each α_k , it follows that $f = f_{\beta}$. Now suppose γ is a vector in V such that $(\alpha|\beta) = (\alpha|\gamma)$ for all α . Then $(\beta - \gamma|\beta - \gamma) = 0$ and $\beta = \gamma$. Thus there is exactly one vector β determining the linear functional f in the stated manner.

The proof of this theorem can be reworded slightly, in terms of the representation of linear functionals in a basis. If we choose an orthonormal basis $\{\alpha_1, \ldots, \alpha_n\}$ for V, the inner product of $\alpha = x_1\alpha_1 + \cdots + x_n\alpha_n$ and $\beta = y_1\alpha_1 + \cdots + y_n\alpha_n$ will be

$$(\alpha|\beta) = x_1\bar{y}_1 + \cdots + x_n\bar{y}_n.$$

If f is any linear functional on V, then f has the form

$$f(\alpha) = c_1 x_1 + \cdots + c_n x_n$$

for some fixed scalars c_1, \ldots, c_n determined by the basis. Of course $c_j = f(\alpha_j)$. If we wish to find a vector β in V such that $(\alpha|\beta) = f(\alpha)$ for all α , then clearly the coordinates y_j of β must satisfy $\bar{y}_j = c_j$ or $y_j = \overline{f(\alpha_j)}$. Accordingly,

$$\beta = \overline{f(\alpha_1)}\alpha_1 + \cdots + \overline{f(\alpha_n)}\alpha_n$$

is the desired vector.

Some further comments are in order. The proof of Theorem 6 that we have given is admirably brief, but it fails to emphasize the essential geometric fact that β lies in the orthogonal complement of the null space of f. Let W be the null space of f. Then $V = W + W^{\perp}$, and f is completely determined by its values on W^{\perp} . In fact, if P is the orthogonal projection of V on W^{\perp} , then

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

$$f(\alpha) = f(P\alpha)$$

for all α in V. Suppose $f \neq 0$. Then f is of rank 1 and dim $(W^{\perp}) = 1$. If γ is any non-zero vector in W^{\perp} , it follows that

$$P\alpha = \frac{(\alpha|\gamma)}{||\gamma||^2} \gamma$$

for all α in V. Thus

$$f(\alpha) = (\alpha|\gamma) \cdot \frac{f(\gamma)}{||\gamma||^2}$$

for all α , and $\beta = \left[\overline{f(\gamma)}/||\gamma||^2\right] \gamma$.

Example

We should give one example showing that Theorem 6 is not true without the assumption that V is finite dimensional. Let V be the vector space of polynomials over the field of complex numbers, with the inner product

$$(f|g) = \int_0^1 f(t)\overline{g(t)} \, dt.$$

This inner product can also be defined algebraically. If $f = \sum a_k x^k$ and $g = \sum b_k x^k$, then

$$(f|g) = \sum_{j,k} \frac{1}{j+k+1} a_j \overline{b_k}.$$

Let z be a fixed complex number, and let L be the linear functional 'evaluation at z':

$$L(f) = f(z).$$

Is there a polynomial g such that (f|g) = L(f) for every f? The answer is no; for suppose we have

$$f(z) = \int_0^1 f(t) \overline{g(t)} dt$$

for every f. Let h = x - z, so that for any f we have (hf)(z) = 0. Then

$$0 = \int_0^1 h(t) f(t) \overline{g(t)} dt$$

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

for all f. In particular this holds when $f = \overline{hg}$ so that

$$\int_0^1 |h(t)|^2 |g(t)|^2 dt = 0$$

and so hg = 0. Since $h \neq 0$, it must be that g = 0. But L is not the zero functional; hence, no such g exists.

One can generalize the example somewhat, to the case where L is a linear combination of point evaluations. Suppose we select fixed complex numbers z_1, \ldots, z_n and scalars c_1, \ldots, c_n and let

$$L(f) = c_1 f(z_1) + \cdots + c_n f(z_n).$$

Then L is a linear functional on V, but there is no g with L(f) = (f|g), unless $c_1 = c_2 = \cdots = c_n = 0$. Just repeat the above argument with $h = (x - z_1) \cdots (x - z_n)$.

Theorem

For any linear operator T on a finite-dimensional inner product space V, there exists a unique linear operator T^* on V such that

(8-14)
$$(\mathbf{T}\alpha|\beta) = (\alpha|\mathbf{T}^*\beta)$$

for all α , β in V.

Proof. Let β be any vector in V. Then $\alpha \to (T\alpha|\beta)$ is a linear functional on V. By Theorem 6 there is a unique vector β' in V such that $(T\alpha|\beta) = (\alpha|\beta')$ for every α in V. Let T^* denote the mapping $\beta \to \beta'$:

 $\beta' = T^*\beta.$

We have (8-14), but we must verify that T^* is a linear operator. Let β , γ be in V and let c be a scalar. Then for any α ,

$$(\alpha|T^*(c\beta + \gamma)) = (T\alpha|c\beta + \gamma)$$

= $(T\alpha|c\beta) + (T\alpha|\gamma)$
= $\overline{c}(T\alpha|\beta) + (T\alpha|\gamma)$
= $\overline{c}(\alpha|T^*\beta) + (\alpha|T^*\gamma)$
= $(\alpha|cT^*\beta) + (\alpha|T^*\gamma)$
= $(\alpha|cT^*\beta + T^*\gamma)$.

Thus $T^*(c\beta + \gamma) = cT^*\beta + T^*\gamma$ and T^* is linear.

The uniqueness of T^* is clear. For any β in V, the vector $T^*\beta$ is uniquely determined as the vector β' such that $(T\alpha|\beta) = (\alpha|\beta')$ for every α .

Theorem

Let V be a finite-dimensional inner product space and let

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

 $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ be an (ordered) orthonormal basis for V. Let T be a linear operator on V and let A be the matrix of T in the ordered basis \mathfrak{B} . Then $A_{kj} = (T\alpha_j | \alpha_k)$.

Proof. Since *B* is an orthonormal basis, we have

$$\alpha = \sum_{k=1}^{n} (\alpha | \alpha_k) \alpha_k.$$

The matrix A is defined by

$$T\alpha_j = \sum_{k=1}^n A_{kj}\alpha_k$$

and since

$$T\alpha_j = \sum_{k=1}^n (T\alpha_j | \alpha_k) \alpha_k$$

we have $A_{kj} = (T\alpha_j | \alpha_k)$.

Corollary. Let V be a finite-dimensional inner product space, and let T be a linear operator on V. In any orthonormal basis for V, the matrix of T^* is the conjugate transpose of the matrix of T.

Proof. Let $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$ be an orthonormal basis for V, let $A = [T]_{\mathfrak{B}}$ and $B = [T^*]_{\mathfrak{B}}$. According to Theorem 8,

$$A_{kj} = (T\alpha_j | \alpha_k)$$
$$B_{kj} = (T^* \alpha_j | \alpha_k)$$

By the definition of T^* we then have

$$B_{kj} = (T^*\alpha_j | \alpha_k)$$

= $\overline{(\alpha_k | T^*\alpha_j)}$
= $\overline{(T\alpha_k | \alpha_j)}$
= $\overline{A_{jk}}$.

Example

Let V be a finite-dimensional inner product space and E the orthogonal projection of V on a subspace W. Then for any vectors α and β in V.

CLASS: III B.Sc MATHEMATICS	COURSE NAME: Ring Th	neory and Linear Algebra-II
COURSE CODE: 17MMU601A	UNIT: IV	BATCH-2017-2020

		<u> </u>
$(E\alpha \beta)$	=	$(E\alpha E\beta + (1-E)\beta)$
	=	$(E\alpha E\beta)$
	=	$(E\alpha + (1-E)\alpha E\beta)$
	-	$(\alpha E\beta).$

From the uniqueness of the operator E^* it follows that $E^* = E$. Now consider the projection E described in Example 14. Then

$$A = \frac{1}{154} \begin{bmatrix} 9 & 36 & -3\\ 36 & 144 & -12\\ -3 & -12 & 1 \end{bmatrix}$$

is the matrix of E in the standard orthonormal basis. Since $E = E^*$, A is also the matrix of E^* , and because $A = A^*$, this does not contradict the preceding corollary. On the other hand, suppose

$$\begin{aligned}
\alpha_1 &= (154, 0, 0) \\
\alpha_2 &= (145, -36, 3) \\
\alpha_3 &= (-36, 10, 12)
\end{aligned}$$

Then $\{\alpha_1, \alpha_2, \alpha_3\}$ is a basis, and

$$E\alpha_1 = (9, 36, -3)$$

$$E\alpha_2 = (0, 0, 0)$$

$$E\alpha_3 = (0, 0, 0).$$

Since (9, 36, -3) = -(154, 0, 0) - (145, -36, 3), the matrix *B* of *E* in the basis $\{\alpha_1, \alpha_2, \alpha_3\}$ is defined by the equation

$$B = \begin{bmatrix} -1 & 0 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

In this case $B \neq B^*$, and B^* is not the matrix of $E^* = E$ in the basis $\{\alpha_1, \alpha_2, \alpha_3\}$. Applying the corollary, we conclude that $\{\alpha_1, \alpha_2, \alpha_3\}$ is not an orthonormal basis. Of course this is quite obvious anyway.

Definition. Let T be a linear operator on an inner product space V. Then we say that T has an adjoint on V if there exists a linear operator T^* on V such that $(T\alpha|\beta) = (\alpha|T^*\beta)$ for all α and β in V.

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

By Theorem 7 every linear operator on a finite-dimensional inner product space V has an adjoint on V. In the infinite-dimensional case this is not always true. But in any case there is at most one such operator T^* ; when it exists, we call it the **adjoint** of T.

Two comments should be made about the finite-dimensional case.

1. The adjoint of T depends not only on T but on the inner product as well.

//

 $= (g|\bar{f}h)$ $= (g|M_{\bar{f}}(h))$

and so $(M_{\bar{f}})^* = M_f$.

Theorem

Let V be a finite-dimensional inner product space. If T and U are linear operators on V and c is a scalar,

- (i) $(T + U)^* = T^* + U^*;$
- (ii) $(cT)^* = \bar{c}T^*;$
- (iii) $(TU)^* = U^*T^*;$
- (iv) $(T^*)^* = T$.

Proof. To prove (i), let α and β be any vectors in V.

Then

$$((T + U)\alpha|\beta) = (T\alpha + U\alpha|\beta)$$

= $(T\alpha|\beta) + (U\alpha|\beta)$
= $(\alpha|T^*\beta) + (\alpha|U^*\beta)$
= $(\alpha|T^*\beta + U^*\beta)$
= $(\alpha|(T^* + U^*)\beta).$

CLASS: III B.Sc MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: IVBATCH-2017-2020

From the uniqueness of the adjoint we have $(T + U)^* = T^* + U^*$. We leave the proof of (ii) to the reader. We obtain (iii) and (iv) from the relations

$$(TU\alpha|\beta) = (U\alpha|T^*\beta) = (\alpha|U^*T^*\beta)$$
$$(T^*\alpha|\beta) = (\overline{\beta|T^*\alpha}) = (\overline{T\beta|\alpha}) = (\alpha|T\beta).$$

Theorem 9 is often phrased as follows: The mapping $T \to T^*$ is a conjugate-linear anti-isomorphism of period 2. The analogy with complex conjugation which we mentioned above is, of course, based upon the observation that complex conjugation has the properties $(\overline{z_1 + z_2}) = \overline{z_1} + \overline{z_2}, (\overline{z_1 z_2}) = \overline{z_1} \overline{z_2}, \overline{\overline{z}} = z$. One must be careful to observe the reversal of order in a product, which the adjoint operation imposes: $(UT)^* = T^*U^*$. We shall mention extensions of this analogy as we continue our study of linear operators on an inner product space. We might mention something along these lines now. A complex number z is real if and only if $z = \overline{z}$. One might expect that the linear operators T such that $T = T^*$ behave in some way like the real numbers. This is in fact the case. For example, if T is a linear operator on a finite-dimensional *complex* inner product space, then

$$(8-15) T = U_1 + iU_2$$

where $U_1 = U_1^*$ and $U_2 = U_2^*$. Thus, in some sense, T has a 'real part' and an 'imaginary part.' The operators U_1 and U_2 satisfying $U_1 = U_1^*$, and $U_2 = U_2^*$, and (8-15) are unique, and are given by

$$U_{1} = \frac{1}{2} (T + T^{*})$$
$$U_{2} = \frac{1}{2i} (T - T^{*}).$$

A linear operator T such that $T = T^*$ is called **self-adjoint** (or **Hermitian**). If \mathcal{B} is an orthonormal basis for V, then

$$[T^*]_{\mathfrak{B}} = [T]^*_{\mathfrak{B}}$$

and so T is self-adjoint if and only if its matrix in every orthonormal basis is a self-adjoint matrix. Self-adjoint operators are important, not simply because they provide us with some sort of real and imaginary part for the general linear operator, but for the following reasons: (1) Self-adjoint operators have many special properties. For example, for such an operator there is an orthonormal basis of characteristic vectors. (2) Many operators which arise in practice are self-adjoint. We shall consider the special properties of self-adjoint operators later.

UNIT-V

Bessel's inequality

Theorem 5. Let W be a finite-dimensional subspace of an inner product space V and let E be the orthogonal projection of V on W. Then E is an idempotent linear transformation of V onto W, W^{\perp} is the null space of E, and

$$V = W \bigoplus W^{\perp}$$
.

Proof. Let β be an arbitrary vector in V. Then $E\beta$ is the best approximation to β that lies in W. In particular, $E\beta = \beta$ when β is in W. Therefore, $E(E\beta) = E\beta$ for every β in V; that is, E is idempotent: $E^2 = E$. To prove that E is a linear transformation, let α and β be any vectors in V and c an arbitrary scalar. Then, by Theorem 4, $\alpha - E\alpha$ and $\beta - E\beta$ are each orthogonal to every vector in W. Hence the vector

 $c(\alpha - E\alpha) + (\beta - E\beta) = (c\alpha + \beta) - (cE\alpha + E\beta)$

also belongs to W^{\perp} . Since $cE\alpha + E\beta$ is a vector in W, it follows from Theorem 4 that

$$E(c\alpha + \beta) = cE\alpha + E\beta.$$

Of course, one may also prove the linearity of E by using (8-11). Again let β be any vector in V. Then $E\beta$ is the unique vector in W such that $\beta - E\beta$ is in W^{\perp} . Thus $E\beta = 0$ when β is in W^{\perp} . Conversely, β is in W^{\perp} when $E\beta = 0$. Thus W^{\perp} is the null space of E. The equation

$$\beta = E\beta + \beta - E\beta$$

shows that $V = W + W^{\perp}$; moreover, $W \cap W^{\perp} = \{0\}$. For if α is a vector in $W \cap W^{\perp}$, then $(\alpha | \alpha) = 0$. Therefore, $\alpha = 0$, and V is the direct sum of W and W^{\perp} .

Theorem 5 implies another result known as Bessel's inequality.

Corollary. Let $\{\alpha_1, \ldots, \alpha_n\}$ be an orthogonal set of non-zero vectors in an inner product space V. If β is any vector in V, then

$$\sum_{\mathbf{k}} rac{|(eta|lpha_{\mathbf{k}})|^2}{||lpha_{\mathbf{k}}||^2} \leq ||eta||^2$$

CLASS: III B. Sc., MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: VBATCH-2017-2020

and equality holds if and only if

$$eta = \sum_{\mathbf{k}} rac{(eta | lpha_{\mathbf{k}})}{|| lpha_{\mathbf{k}} ||^2} \, lpha_{\mathbf{k}}$$

Proof. Let
$$\gamma = \sum_{k} \left[(\beta |\alpha_k) / ||\alpha_k||^2 \right] \alpha_k$$
. Then $\beta = \gamma + \delta$ where

 $(\gamma|\delta) = 0$. Hence

 $||\beta||^2 = ||\gamma||^2 + ||\delta||^2.$

It now suffices to prove that

$$||\gamma||^2 = \sum_k \frac{|(\beta|\alpha_k)|^2}{||\alpha_k||^2}$$

This is straightforward computation in which one uses the fact that $(\alpha_j | \alpha_k) = 0$ for $j \neq k$.

Theorem 9 (Spectral Theorem). Let T be a normal operator on a finite-dimensional complex inner product space V or a self-adjoint operator on a finite-dimensional real inner product space V. Let c_1, \ldots, c_k be the distinct characteristic values of T. Let W_i be the characteristic space associated with c_i and E_i the orthogonal projection of V on W_i . Then W_i is orthogonal to W_i when $i \neq j$, V is the direct sum of W_1, \ldots, W_k , and

 $(9-11) T = c_1 E_1 + \cdots + c_k E_k.$

Proof. Let α be a vector in W_j , β a vector in W_i , and suppose $i \neq j$. Then $c_j(\alpha|\beta) = (T\alpha|\beta) = (\alpha|T^*\beta) = (\alpha|\bar{c}_i\beta)$. Hence $(c_j - c_i)(\alpha|\beta) = 0$, and since $c_j - c_i \neq 0$, it follows that $(\alpha|\beta) = 0$. Thus W_j is orthogonal to W_i when $i \neq j$. From the fact that V has an orthonormal basis consisting of characteristic vectors (cf. Theorems 18 and 22 of Chapter 8), it follows that $V = W_1 + \cdots + W_k$. If α_j belongs to V_j $(1 \leq j \leq k)$ and $\alpha_1 + \cdots + \alpha_k = 0$, then

$$0 = (\alpha_i | \sum_j \alpha_j) = \sum_j (\alpha_i | \alpha_j)$$
$$= ||\alpha_i||^2$$

for every *i*, so that *V* is the direct sum of W_1, \ldots, W_k . Therefore $E_1 + \cdots + E_k = I$ and

$$T = TE_1 + \cdots + TE_k$$

= $c_1E_1 + \cdots + c_kE_k$.

CLASS: III B. Sc., MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: VBATCH-2017-2020

Corollary. If
$$e_i = \prod_{i \neq j} \left(\frac{x - e_i}{e_j - e_i} \right)$$
, then $E_i = e_j(T)$ for $1 \leq j \leq k$
Proof. Since $E_i E_i = 0$ when $i \neq i$, it follows that

 $T^2 = c_1^2 E_1 + \cdots + c_k^2 E_k$

and by an easy induction argument that

$$T^n = c_1^n E_1 + \cdots + c_k^n E_k$$

for every integer $n \ge 0$. For an arbitrary polynomial

$$f=\sum_{n=0}^r a_n x^n$$

we have

$$f(T) = \sum_{n=0}^{r} a_n T^n$$

=
$$\sum_{n=0}^{r} a_n \sum_{j=1}^{k} c_j^n E_j$$

=
$$\sum_{j=1}^{k} \left(\sum_{n=0}^{r} a_n c_j^n \right) E_j$$

=
$$\sum_{j=1}^{k} f(c_j) E_j.$$

Since $e_j(c_m) = \delta_{jm}$, it follows that $e_j(T) = E_j$.

CLASS: III B. Sc., MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: VBATCH-2017-2020

Theorem 10. Let T be a diagonalizable normal operator with spectrum S on a finite-dimensional inner product space V. Suppose f is a function whose domain contains S that has values in the field of scalars. Then f(T) is a diagonalizable normal operator with spectrum f(S). If U is a unitary map of V onto V' and T' = UTU⁻¹, then S is the spectrum of T' and

$$f(T') = Uf(T)U^{-i}.$$

Proof. The normality of f(T) follows by a simple computation from (9-12) and the fact that

$$f(T)^* = \sum_j \overline{f(c_j)} E_j.$$

Moreover, it is clear that for every α in $E_j(V)$

$$f(T)\alpha = f(c_j)\alpha.$$

Thus, the set f(S) of all f(c) with c in S is contained in the spectrum of f(T). Conversely, suppose $\alpha \neq 0$ and that

$$f(T)\alpha = b\alpha.$$

Then $\alpha = \sum_{j} E_{j} \alpha$ and

$$f(T)\alpha = \sum_{j} f(T)E_{j}\alpha$$
$$= \sum_{j} f(c_{j})E_{j}\alpha$$
$$= \sum_{j} bE_{j}\alpha.$$

Hence,

$$\frac{||\sum_{j} (f(c_{j}) - b)E_{j}\alpha||^{2}}{= \sum_{j} |f(c_{j}) - b|^{2}||E_{j}\alpha||^{2}}$$

= 0

Therefore, $f(c_i) = b$ or $E_i \alpha = 0$. By assumption, $\alpha \neq 0$, so there exists an index *i* such that $E_i \alpha \neq 0$. It follows that $f(c_i) = b$ and hence that f(S) is the spectrum of f(T). Suppose, in fact, that

$$f(S) = \{b_1,\ldots,b_r\}$$

where $b_m \neq b_n$ when $m \neq n$. Let X_m be the set of indices *i* such that $1 \leq i \leq k$ and $f(c_i) = b_m$. Let $P_m = \sum_i E_i$, the sum being extended over

CLASS: III B. Sc., MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: VBATCH-2017-2020

the indices i in X_m . Then P_m is the orthogonal projection of V on the subspace of characteristic vectors belonging to the characteristic value b_m of f(T), and

$$f(T) = \sum_{m=1}^{r} b_m P_m$$

is the spectral resolution of f(T).

Now suppose U is a unitary transformation of V onto V' and that $T' = UTU^{-1}$. Then the equation

$$T\alpha = c\alpha$$

holds if and only if

$$T'U\alpha = cU\alpha.$$

Thus S is the spectrum of T', and U maps each characteristic subspace for T onto the corresponding subspace for T'. In fact, using (9-12), we see that

$$T' = \sum_{j} c_{j} E'_{j}, \qquad E'_{j} = U E_{j} U^{-1}$$

is the spectral resolution of T'. Hence

$$\begin{split} f(T') &= \sum_{j} f(c_{j}) E'_{j} \\ &= \sum_{j} f(c_{j}) U E_{j} U^{-1} \\ &= U \left(\sum_{j} f(c_{j}) E_{j} \right) U^{-1} \\ &= U f(T) U^{-1}. \end{split}$$

Definition. Let V be a finite-dimensional inner product space and T a linear operator on V. We say that T is **normal** if it commutes with its adjoint *i.e.*, $TT^* = T^*T$.

CLASS: III B. Sc., MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: VBATCH-2017-2020

Theorem 15. Let V be an inner product space and T a self-adjoint linear operator on V. Then each characteristic value of T is real, and characteristic vectors of T associated with distinct characteristic values are orthogonal.

Proof. Suppose c is a characteristic value of T, i.e., that $T\alpha = c\alpha$ for some non-zero vector α . Then

 $c(\alpha|\alpha) = (c\alpha|\alpha)$ = $(T\alpha|\alpha)$ = $(\alpha|T\alpha)$ = $(\alpha|c\alpha)$ = $\overline{c}(\alpha|\alpha)$.

Since $(\alpha | \alpha) \neq 0$, we must have $c = \overline{c}$. Suppose we also have $T\beta = d\beta$ with $\beta \neq 0$. Then

$c(\alpha \beta)$	=	$(T\alpha \beta)$
	-	$(\alpha T\beta)$
	=	$(\alpha d\beta)$
		$\bar{d}(lpha eta)$
	-	$d(\alpha \beta).$

If $c \neq d$, then $\langle \alpha | \beta \rangle = 0$.

Theorem 16. On a finite-dimensional inner product space of positive dimension, every self-adjoint operator has a (non-zero) characteristic vector.

Proof. Let V be an inner product space of dimension n, where n > 0, and let T be a self-adjoint operator on V. Choose an orthonormal basis \mathfrak{G} for V and let $A = [T]_{\mathfrak{G}}$. Since $T = T^*$, we have $A = A^*$. Now let W be the space of $n \times 1$ matrices over C, with inner product $(X|Y) = Y^*X$. Then U(X) = AX defines a self-adjoint linear operator U on W. The characteristic polynomial, det (xI - A), is a polynomial of degree n over the complex numbers; every polynomial over C of positive degree has a root. Thus, there is a complex number c such that det (cI - A) = 0. This means that A - cI is singular, or that there exists a non-zero X such that AX = cX. Since the operator U (multiplication by A) is self-adjoint, it follows from Theorem 15 that c is real. If V is a real vector space, we may choose X to have real entries. For then A and A - cI have real entries, and since A - cI is singular, the system (A - cI)X = 0 has a non-zero real solution X. It follows that there is a non-zero vector α in V such that $T\alpha = c\alpha$.

CLASS: III B. Sc., MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: VBATCH-2017-2020

Theorem 17. Let V be a finite-dimensional inner product space, and let T be any linear operator on V. Suppose W is a subspace of V which is invariant under T. Then the orthogonal complement of W is invariant under T^* .

Proof. We recall that the fact that W is invariant under T does not mean that each vector in W is left fixed by T; it means that if α is in W then $T\alpha$ is in W. Let β be in W^{\perp} . We must show that $T^*\beta$ is in W^{\perp} , that is, that $(\alpha|T^*\beta) = 0$ for every α in W. If α is in W, then $T\alpha$ is in W, so $(T\alpha|\beta) = 0$. But $(T\alpha|\beta) = (\alpha|T^*\beta)$.

Theorem 22. Let V be a finite-dimensional complex inner product space and T a normal operator on V. Then V has an orthonormal basis consisting of characteristic vectors for T.

Again there is a matrix interpretation.

Theorem 18. Let V be a finite-dimensional inner product space, and let T be a self-adjoint linear operator on V. Then there is an orthonormal basis for V, each vector of which is a characteristic vector for T.

Proof. We are assuming dim V > 0. By Theorem 16, T has a characteristic vector α . Let $\alpha_1 = \alpha/||\alpha||$ so that α_1 is also a characteristic vector for T and $||\alpha_1|| = 1$. If dim V = 1, we are done. Now we proceed by induction on the dimension of V. Suppose the theorem is true for inner product spaces of dimension less than dim V. Let W be the one-dimensional subspace spanned by the vector α_1 . The statement that α_1 is a characteristic vector for T simply means that W is invariant under T. By Theorem 17, the orthogonal complement W^{\perp} is invariant under $T^* = T$. Now W^{\perp} , with the inner product from V, is an inner product space of dimension one less than the dimension of V. Let U be the linear operator induced on W^{\perp} by T, that is, the restriction of T to W^{\perp} . Then U is self-adjoint, and by the induction hypothesis, W^{\perp} has an orthonormal basis $\{\alpha_2, \ldots, \alpha_n\}$ consisting of characteristic vectors for T, and since $V = W \bigoplus W^{\perp}$, we conclude that $\{\alpha_1, \ldots, \alpha_n\}$ is the desired basis for V.

CLASS: III B. Sc., MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: VBATCH-2017-2020

Theorem 19. Let V be a finite-dimensional inner product space and T a normal operator on V. Suppose α is a vector in V. Then α is a characteristic vector for T with characteristic value c if and only if α is a characteristic vector for T* with characteristic value \overline{c} .

Proof. Suppose U is any normal operator on V. Then $||U\alpha|| = ||U^*\alpha||$. For using the condition $UU^* = U^*U$ one sees that

$$\begin{aligned} ||U\alpha||^2 &= (U\alpha|U\alpha) = (\alpha|U^*U\alpha) \\ &= (\alpha|UU^*\alpha) = (U^*\alpha|U^*\alpha) = ||U^*\alpha||^2. \end{aligned}$$

If c is any scalar, the operator U = T - cI is normal. For $(T - cI)^* = T^* - \bar{c}I$, and it is easy to check that $UU^* = U^*U$. Thus

$$||(T - cI)\alpha|| = ||(T^* - cI)\alpha||$$

so that $(T - cI)\alpha = 0$ if and only if $(T^* - \overline{c}I)\alpha = 0$.

Definition. A complex $n \times n$ matrix A is called normal if $AA^* = A^*A$.

Theorem 20. Let V be a finite-dimensional inner product space, T a linear operator on V, and \mathfrak{B} an orthonormal basis for V. Suppose that the matrix A of T in the basis \mathfrak{B} is upper triangular. Then T is normal if and only if A is a diagonal matrix.

Proof. Since \mathfrak{B} is an orthonormal basis, A^* is the matrix of T^* in \mathfrak{B} . If A is diagonal, then $AA^* = A^*A$, and this implies $TT^* = T^*T$. Conversely, suppose T is normal, and let $\mathfrak{B} = \{\alpha_1, \ldots, \alpha_n\}$. Then, since A is upper-triangular, $T\alpha_1 = A_{11}\alpha_1$. By Theorem 19 this implies, $T^*\alpha_1 = \overline{A_{11}\alpha_1}$. On the other hand,

$$T^* \alpha_1 = \sum_j (A^*)_{j1} \alpha_j$$
$$= \sum_j \bar{A}_{1j} \alpha_j.$$

Therefore, $A_{1j} = 0$ for every j > 1. In particular, $A_{12} = 0$, and since A is upper-triangular, it follows that

$$T\alpha_2 = A_{22}\alpha_2.$$

Thus $T^*\alpha_2 = \tilde{A}_{22}\alpha_2$ and $A_{2j} = 0$ for all $j \neq 2$. Continuing in this fashion, we find that A is diagonal.

KARPAGAM ACADEMY OF HIGHER EDUCATION CLASS: III B. Sc., MATHEMATICS COURSE NAME: Ring Theory and Linear Algebra-II

COURSE CODE: 17MMU601AUNIT: VBATCH-2017-2020

Theorem 21. Let V be a finite-dimensional complex inner product space and let T be any linear operator on V. Then there is an orthonormal basis for V in which the matrix of T is upper triangular.

Proof. Let n be the dimension of V. The theorem is true when n = 1, and we proceed by induction on n, assuming the result is true for linear operators on complex inner product spaces of dimension n - 1. Since V is a finite-dimensional complex inner product space, there is a unit vector α in V and a scalar c such that

$$T^*\alpha = c\alpha.$$

Let W be the orthogonal complement of the subspace spanned by α and let S be the restriction of T to W. By Theorem 17, W is invariant under T. Thus S is a linear operator on W. Since W has dimension n - 1, our inductive assumption implies the existence of an orthonormal basis $\{\alpha_1, \ldots, \alpha_{n-1}\}$ for W in which the matrix of S is upper-triangular; let $\alpha_n = \alpha$. Then $\{\alpha_1, \ldots, \alpha_n\}$ is an orthonormal basis for V in which the matrix of T is upper-triangular.

Corollary. For every complex $n \times n$ matrix A there is a unitary matrix U such that U⁻¹AU is upper-triangular.

Theorem 12. Let T be a diagonalizable normal operator on a finitedimensional inner product space V. Then T is self-adjoint, non-negative, or unitary according as each characteristic value of T is real, non-negative, or of absolute value 1.

Proof. Suppose T has the spectral resolution $T = c_1E_1 + \cdots + c_kE_k$, then $T^* = \bar{c}_1E_1 + \cdots + \bar{c}_kE_k$. To say T is self-adjoint is to say $T = T^*$, or

 $(c_1-\overline{c}_1)E_1+\cdots+(c_k-\overline{c}_k)E_k=0.$

Using the fact that $E_i E_j = 0$ for $i \neq j$, and the fact that no E_j is the zero operator, we see that T is self-adjoint if and only if $c_j = \bar{c}_j, j = 1, \ldots, k$. To distinguish the normal operators which are non-negative, let us look at

$$(T\alpha|\alpha) = \left(\sum_{j=1}^{k} c_j E_j \alpha | \sum_{i=1}^{k} E_i \alpha\right)$$
$$= \sum_{i} \sum_{j} c_j (E_j \alpha | E_i \alpha)$$
$$= \sum_{j} c_j ||E_j \alpha||^2.$$

CLASS: III B. Sc., MATHEMATICSCOURSE NAME: Ring Theory and Linear Algebra-IICOURSE CODE: 17MMU601AUNIT: VBATCH-2017-2020

We have used the fact that $(E_j\alpha|E_i\alpha) = 0$ for $i \neq j$. From this it is clear that the condition $(T\alpha|\alpha) \geq 0$ is satisfied if and only if $c_j \geq 0$ for each j. To distinguish the unitary operators, observe that

$$TT^* = c_1 c_1 E_1 + \cdots + c_k c_k E_k = |c_1|^2 E_1 + \cdots + |c_k|^2 E_k.$$

If $TT^* = I$, then $I = |c_1|^2 E_1 + \cdots + |c_k|^2 E_k$, and operating with E_j

$$E_j = |c_j|^2 E_j.$$

Since $E_j \neq 0$, we have $|c_j|^2 = 1$ or $|c_j| = 1$. Conversely, if $|c_j|^2 = 1$ for each j, it is clear that $TT^* = I$.
