17ITU601A

PHP PROGRAMMING

4H - 4C

Instruction Hours / week: L: 3 T: 0 P: 0 Marks: Int: 40 Ext: 60 Total: 100

SCOPE

This course design focuses on the structure of the website including the information architecture, the layout or the pages and the conceptual design with branding. PHP helps the students for developing dynamic web pages.

OBJECTIVES

- To work with open source applications that deal with database and website development.
- Establish a working environment for PHP web page development
- Very familiar with GUI, coded, modified controls

UNIT-I

Introduction to PHP:

PHP introduction, inventions and versions, important tools and software requirements (like Web Server, Database, Editors etc.) -PHP with other technologies, scope of PHP Basic Syntax, PHP variables and constants-Types of data in PHP, Expressions, scopes of a variable (local, global)-PHP Operators: Arithmetic, Assignment, Relational, Logical operators, Bitwis, ternary and MOD operator.-PHP operator Precedence and associativity

UNIT-II

Handling HTML form with PHP:

Capturing Form Data -GETand POST form methods- Dealing with multi value fields - Redirecting a form after submission -**PHP conditional events and Loops:** PHP IF Else conditional statements (Nested IF and Else) -Switch case, while ,For and Do While Loop - Goto , Break ,Continue and exit

UNIT-III

PHP Functions:

Function, Need of Function , declaration and calling of a function-PHP Function with arguments, Default Arguments in Function-Function argument with call by value, call by reference-Scope of Function Global and Local

UNIT-IV

String Manipulation and Regular Expression: (3L) Creating and accessing String, Searching & Replacing String-Formatting, joining and splitting String, String Related Library functions -Use and advantage of regular expression over inbuilt function-Use of preg_match(), preg_replace(), preg_split() functions in regular expression.

UNIT-V Array:

Anatomy of an Array ,Creating index based and Associative array ,Accessing array

- -Looping with Index based array, with associative array using each() and foreach()
- -Some useful Library function

Suggested Readings

- 1. Steven Holzner. (2007). PHP: The Complete Reference. New Delhi: McGraw Hill Education (India).
- 2. Timothy Boronczyk., & Martin, E. Psinas. (2008). PHP and MYSQL (Create-Modify-Reuse). New Delhi: Wiley India Private Limited.
- 3. Robin Nixon. (2014). Learning PHP, MySQL, JavaScript, CSS & HTML5 (3rd ed.). O'reilly.
- 4. Luke Welling., & Laura Thompson. (2008). PHP and MySQL Web Development (4th ed.). Addition Paperback, Addison-Wesley Professional.
- 5. David Sklar., & Adam Trachtenberg. PHP Cookbook: Solutions & Examples for PHP.

SUBJECT : PHP Programming

SEMESTER: VI

SUBJECT CODE: 17ITU601A CLASS : III B.Sc (IT)

LECTURE PLAN

S.NO	LECTURE DURATION (Hour)	TOPICS TO BE COVERED	SUPPORT MATERIALS			
	UNIT I					
1.	1	Introduction to PHP: PHP introduction	S1:1,W1			
2.	1	Inventions and versions	S1:1			
3.	1	Important tools and software requirements PHP with other technologies	W1, S3:15-43,S3:5-10			
4.	1	Scope of PHP	S3:66-70			
5.	1	Basic Syntax PHP variables and constants	S3:49,S1:26-30,35-36, S3:50-55,63-64			
6.	1	Types of data in PHP Expressions, scopes of a variable	S3:62,W2 S3:73-75			
7.	1	PHP Operators:	S1:41-52			
8.	1	PHP Operator Precedence and associativity	S1:53-55, S3:76-80			
9.	1					
		Total No. of Hours Planned for Unit-I	9 Hrs			
		UNIT II				
1.	1	Handling HTML form with PHP: Capturing Form Data				
2.	1	GET and POST form methods	S1:161-195, W3,W4			
3.	1	Dealing with multi value fields	W 3, W 1			
4.	1	Redirecting a form after submission				
5.	1	PHP conditional events and Loops:				
6.	1	While, For and Do While Loop	S1:69-76			
7.	1	Goto , Break ,Continue and exit	S3:97-98			
8.	1	Recapitulation and Discussion of important questions				
_		Total No. of Hours Planned for Unit-II	8 Hrs			

		UNIT III	
1.	1	PHP Functions: Function, Need of Function	S1:123-125 S3:103-106
2.	1	Declaration and calling of a function	S1:125-127,W4
3.	1	PHP Function with arguments	S1:127-130,W4
4.	1	Default Arguments in Function	S1:132-133
5.	1	Function argument with call by value Function argument with call by reference	S1:133-135 S1:130-132
6.	1	Scope of Function Global and Local	S1:145, S3:111
7.	1	Recapitulation and Discussion of important questions	55.111
		Total No. of Hours Planned for Unit-III	7 Hrs
		UNIT IV	
1.	1	String Manipulation and Regular Expression Creating and accessing String , Searching & Replacing String	S1:83-84 S4:115,S5:1-8
2.	1	Formatting, joining and splitting String	S5:10-18
3.	1	String Related Library functions S4:116,Wo	
4.	1	Use and advantage of regular expression over inbuilt function S3:396-397,W2	
5.	1	Use of preg_match(), preg_replace ()	S5:651-657, S5:12- 14,W5,W7
6.	1	preg_split() functions in regular expression.	S5:25-27,W5,W7
7.	1	Recapitulation and Discussion of important questions	
		Total No. of Hours Planned for Unit-IV	7 Hrs
		UNIT V	
1.	1	Array: Anatomy of an Array	S3:131,W7
2.	1	Creating index based	
3.	1	Associative array Accessing array	S3:131-134
4.	1	Looping with Index based array	S3:131,W7
5.	1	associative array using each() and for each()	S3:135-137
6.	1	Some useful Library function	S3:140-144,W8
7.	1	Recapitulation and Discussion of important questions	
8.	1	Previous Year ESE Questions Discussion	
9.	1	Previous Year ESE Questions Discussion	
		Total No. of Hours Planned for Unit-V	9 Hrs

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

UNIT-I

Introduction to PHP:

PHP introduction, inventions and versions, important tools and software requirements (like Web Server, Database, Editors etc.) -PHP with other technologies, scope of PHP Basic Syntax, PHP variables and constants-Types of data in PHP, Expressions, scopes of a variable (local, global)-PHP Operators: Arithmetic, Assignment, Relational, Logical operators, Bitwise, ternary and MOD operator.-PHP operator Precedence and associativity

PHP INTRODUCTION:

Introduction to PHP

PHP is a simple yet powerful language designed for creating HTML content. This chapter covers essential background on the PHP language. It describes the nature and history of PHP, which platforms it runs on, and how to configure it. This chapter ends by showing you PHP in action, with a quick walkthrough of several PHP programs that illustrate common tasks, such as processing form data, interacting with a database, and creating graphics.

What is PHP

An established server-side, cross platform embedded HTML scripting language for creating dynamic Web pages. PHP provides many features that commercial entities are looking for

What Does PHP Do?

PHP can be used in three primary ways:

1. Server-side scripting

PHP was originally designed to create dynamic web content, and it is still best suited for that task. To generate HTML, you need the PHP parser and a web server through which to send the coded documents. PHP has also become popular for generating XML documents, graphics, Flash animations, PDF files, and so much more.

2. Command-line scripting

PHP can run scripts from the command line, much like Perl, awk, or the Unix shell.

You might use the command-line scripts for system administration tasks, such as backup and log parsing; even some CRON job type scripts can be done this way (nonvisual PHP tasks).

3. Client-side GUI applications

Using PHP-GTK, you can write full-blown, cross-platform GUI applications in PHP.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

Characteristics of PHP

Five important characteristics make PHP's practical nature possible:

- > Simplicity
- > Efficiency
- Security
- > Flexibility
- > Familiarity

PHP Advantages

- Exceptionally short learning curve
- ➤ Quick development time
- Very high performance
- ➤ It supports all major platforms (UNIX, Windows and even mainframes).
- Features native support for most popular databases

INVENTION AND VERSIONS OF PHP

The first version of what came to be known as PHP was created in 1995 by a man named Rasmus Lerdof. Rasmus, now an engineer at Yahoo!, needed something to make it easier to create content on his web site, something that would work well with HTML, yet give him power and flexibility beyond what HTML could offer him. Essentially, what he needed was an easy way to write scripts that would run on his web server both to create content, and handle data being passed back to the server from the web browser. Using the Perl language, he created some technology that gave him what he needed and decided to call this technology "Personal Home Page/Forms Interpreter". The technology provided a convenient way to process web forms and create content.

The name "Personal Home Page/Forms Interpreter" was later shortened to PHP/FI and eventually renamed to represent "PHP: Hypertext Preprocessor". The name is said to be recursive because the full name also includes the acronym "PHP" - an odd geeky joke that is common in technology circles when people have trouble naming things. GNU is another recursive name that represents "GNU's Not Unix".

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

PHP/FI version 1.0 was never really used outside of Rasmus' own web site. With the introduction of PHP/FI 2.0 this began to change. When PHP 3 was released in 1997, adoption of PHP exploded beyond all belief.

PHP 3 Hits the Big Time

By the time 1997 arrived the number of web sites on the internet was growing exponentially and most of these web sites were being implemented using the Apache web server. It was around this time that Andy Gutmans and Zeev Suraski launched the PHP 3 project, a project designed to take PHP to the next level. One of the key achievements of the PHP 3 project was to implement PHP as a robust Apache Module.

PHP 3 was implemented using a modular approach that made it easy for others to extend functionality, and also introduced the first elements of object-orientation that would continue to evolve through subsequent releases.

The combination of PHP 3 and Apache quickly lead to the widespread adoption of PHP, and it is commonly estimated that, at its peak adoption level, PHP3 was used to power over 10% of all web sites on the internet.

PHP 4 - Optimization, Scalability and More

With PHP 4 Andi Gutmans and Zeev Suraski once again re-architected PHP from the ground up. PHP 4 was built upon a piece of technology called the Zend Engine. The move to the Zend Engine brought about a number of key improvements in PHP:

- Support for other web servers (Microsoft's Internet Information Server (IIS) being of particular significance).
- Improved memory handling to avoid memory leaks (one of the most difficult types of problems to isolate in a program).
- Improved efficiency and performance to support large scale, complex, mission critical enterprise application development using PHP.

In addition PHP 4 also built on the earlier Object Oriented Programming features of PHP 3 with the introduction of classes.

PHP 5 - Object Orientation, Error Handling and XML

The main, though far from only, feature of PHP 5 is the improved support for Object Oriented Programming (OOP). In addition, PHP 5 introduced some features common in other languages such as Java like try/catch error and exception handling.

KARPAGAM ACADEMY OF HIGHER EDUCATION (General to be University)

KARPAGAM ACADEMY OF HIGHER EDUCATION

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

PHP 5 also introduced new extensions aimed at easing the storage and manipulation of data. Significant new features include SimpleXML for handling XML documents, and SQLite, an embedded basic and easy to use database interface.

PHP 6: In this version, ICU (International Components for Unicode) library wasembedded into the program. But due to several other reasons this version was abandoned and was not launched in the market.

PHP 7: This is the newest version of the php programming language having several features which were not present in the previous versions such as 64-bit integer support, return and scalar type declarations etc. It is powered by Zend Engine 3.

IMPORTANT TOOLS AND SOFTWARE REQUIREMENTS

The three types of tools for PHP:

- > Tools for writing code
- > A file transfer program
- ➤ A local Web server

Software Requirements

PHPKB knowledge base software is very simple to install and easy to configure PHP script on your web server. If required, we also offer a free installation service of our knowledge management software on your web-server. It requires the following:

User Requirements

- Operating System: Windows, Mac or Linux
- Web Browser: All industry standard web browsers (Internet Explorer, Mozilla Firefox, Google Chrome, Apple Safari)

Web Server Requirements

You need to be running PHP 5.3+ & MySQL 4.1+ on a web server (Apache/IIS). PHPKB knowledge base software has been deployed successfully on both Apache and IIS web servers.

- Operating System: Linux, Unix, Windows
- Web Server: Apache Web Server, LigHTTPD, IIS (with ISAPI_Rewrite installed)
- PHP Version:
 - o For MySQL Editions, PHP 5.3 or above with PHP XML extension enabled.
 - For SQL Server Editions, PHP 5.3 or above with PHP XML extension enabled and Microsoft SQL Server Driver for PHP

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

- Database: MySQL 4.1 or above, Microsoft SQL Server 2005 or above.
- Optional Requirements
 - o Apache's mod_rewrite() extension to allow for SEO friendly URLs.
 - PHP <u>LDAP library</u> is required to use LDAP functionality in the Enterprise edition
 - AntiWord (free) is required to index and search Microsoft Word 2003/XP documents
 - ppthtml (free) is required to index and search Microsoft PowerPoint 2003/XP documents
 - PHP <u>zip library</u> (free) is required to index and search Microsoft Word/PowerPoint 2007 documents
 - o <u>pdftohtml</u> (free) is required to index and search Adobe PDF documents

Requirement Details

Apache (Recommended)

PHPKB will work on Apache 1.3 or Apache 2.x hosted on UNIX/Linux, OS X, or Windows. The majority of PHPKB development and deployment is done on Apache, so there is more community experience and testing performed on Apache than on other web servers. You can use the Apache 'mod_rewrite' extension to allow for SEO friendly URLs.

Microsoft IIS

PHPKB will work using IIS 5, IIS 6, IIS 7 or later, if PHP is configured correctly. To achieve SEO friendly URLs you may need to use a third party product. For IIS7 (or later), you can use the Microsoft URL Rewrite Module or a third party solution such as <u>ISAPI Rewrite</u>. ISAPI_Rewrite is Apache mod_rewrite compatible URL rewriter for Microsoft IIS.

Disk Space

A minimum base installation requires at least 8MB of disk space but you should assume that your actual disk space will be somewhat higher. For example, if you upload file attachments and images for articles, the actual disk space for your knowledge base could easily be 20 MB or more (exclusive of database content, media, backups and other files).

The total file size of your PHPKB installation will depend on what you add to your knowledge base, but core files alone will take up approximately 7 to 9 MB uncompressed. The exact size depends on the edition of PHPKB you have installed.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

Browsers

All modern browsers are supported (IE7+, Firefox, Safari, Google Chrome, Opera) that support CSS and JavaScript.

Recommended Hardware Requirements

PHPKB knowledge base software works well on any web-server that meets its software requirements specified above. This is definitely not a processor-hungry or memory-hungry application. Numerous instances of PHPKB knowledge base software are running on shared web hosting (virtual hosting) systems and are working perfectly fine. It means you can install it on a shared hosting server too. If you would like to use a dedicated hosting or host it on a local server, you can have a look at the hardware requirements and example configurations for a reference.

PHP Server

The PHP Community Provides Some types of Software Server solution under The GNU (General Public License).

These are the following:

- 1. WAMP Server
- 2. LAMP Server
- 3. MAMP Server
- 4. XAMPP Server

All these types of software automatic configure inside operating system after installation it having PHP, MySQL, Apache and operating system base configuration file, it doesn't need to configure manually.

Server	Stands for
WAMP	Microsoft window o/s, Apache, Mysql, PHP
LAMP	Linux Operating System, Apache, Mysql, PHP
MAMP	Mac os, Apache, Mysql, PHP,
XAMPP	x-os(cross operating system), Apache, Mysql, PHP,Perl

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

SCOPE OF PHP

PHP Visibility over internet: securing php future

- If you surf net, you can easily find out many websites with extension '.php'. This vast availability of php applications on internet can make you think about its popularity.
- Currently PHP pages are a common part of web applications, and one of the most popular languages for web development used by developers worldwide.
- If we surf internet we can see millions of websites built with php and mysql.

PHP in blogging: a secure scope of php

- Excellent blog webistes are built using wordpress, which is also designed by PHP.
- Blogs are the most common contents of internet in today's world. People with minimum technical knowledge operates their Blogs, this is possible by simple language like php.

CMS Supporting PHP: a Technical Future Move

- Thousands of CMS that support PHP are freely available to download and use like Zend, Codeigniter, YUii, symfony, <u>Joomla</u>, <u>Magento</u>, <u>Drupal</u> and Cake php etc.
- CMS in support to PHP provides the efficient way to publish websites easily, which is a very good move for the future of PHP.

PHP and MySQL: providing vast range application

- The combination of PHP and MySQL provides a vast range of web application development.
- Web application development for even non-technical persons have become simple with combo of PHP and MySQL database.

PHP simplicity uplifting its use in future

- PHP is so simple and easy to use, that makes its future bright as working on other languages is more complex than PHP.
- PHP came in lame light after over taking many powerful languages in web development, this justifies that PHP is going to be in market for long lasting.

Regular updation in PHP: a way to maintain future existence

- Day by day modification for using PHP is being done by developing new technologies, new frameworks.
- New frameworks are coming in existence to support PHP coding, this is a measure for PHP future.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

- Object oriented based frameworks like zend is in market that is working like a booster for PHP web application development.
- CMS that supports working on PHP provides extendable plug-ins to extend the features for using PHP.

Recommendations: increase in popularity and future scope of PHP

- Many professionals from top companies prefer using PHP for web application development.
- PHP is used over other languages because it's above mentioned benefits.
- PHP is also a low cost web development tool, developers charge very less or we may say low development charge is allotted. As a result companies prefer it more.
- For the developers who are fresher to PHP, for them also PHP is a very good and effective tool to start with.
- If you want to continue your job as a developer itself, then PHP or any other tool/language is just a technology, more focus should be on your logics.
- Logics are the important tool for your survival as the code developer

BASIC PHP SYNTAX

A PHP script can be placed anywhere in the document.

Canonical PHP Tags:

The script starts with <?php and ends with ?> . These tags are also called 'Canonical PHP tags'.

A PHP script starts with <?php and ends with ?>:

Syntax

<pphp</pre>

// PHP code goes here

2>

The default file extension for PHP files is ".php".

A PHP file normally contains HTML tags, and some PHP scripting code.

Below, we have an example of a simple PHP file, with a PHP script that uses a built-in PHP function "echo" to output the text "Hello World!" on a web page:

Semicolons

PHP commands ended with a semicolon, like this:

x += 10;

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

Probably the most common cause of errors you will encounter with PHP is forgetting this semicolon. This causes PHP to treat multiple statements like one statement, which it is unable to understand, prompting it to produce a Parse error message.

```
Example
<!DOCTYPE html>
<html>
<body>
<h1>My first PHP page</h1>
<!Pphp
echo "Hello World!";
?>
</body>
</html>
```

The \$ symbol

The \$ symbol has come to be used in many different ways by different programming languages. For example, if you have ever written in the BASIC language, you will have used the \$ to terminate variable names to denote them as strings.

In PHP, however, you must place a \$ in front of *all* variables. This is required to make the PHP parser faster, as it instantly knows whenever it comes across a variable.

Example: Three different types of variable assignment

```
<Pphp
$mycounter = 1;
$mystring = "Hello";
$myarray = array("One", "Two", "Three");
P>
```

COMMENTS IN PHP

A comment is something which is ignored and not read or executed by PHP engine or the language as part of a program and is written to make the code more readable and understandable. These are used to help other users and developers to describe the code and what it is trying to do. It can also be used in documenting a set of code or part of a program. You must have noticed this in above sample programs. PHP supports two types of comment:

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

Single Line Comment: As the name suggests these are single line or short relevant explanations that one can add in there code. To add this, we need to begin the line with (//) or (#).

```
Example:
<!php
// This is a single line comment
// These cannot be extended to more lines
echo "hello world!!!";
# This is also a single line comment
P>
```

Multi-line or Multiple line Comment: These are used to accommodate multiple lines with a single tag and can be extended to many lines as required by the user. To add this, we need to begin and end the line with (/*...*/)

<?php

/* This is a multi line comment

In PHP variables are written

by adding a \$ sign at the beginning.*/

\$geek = "hello world!";

echo \$geek;

5>

PHP VARIABLES

A variable in PHP is a name of memory location that holds data. A variable is a temporary storage that is used to store data temporarily.

A variable can have a short name (like x and y) or a more descriptive name (age, carname, total volume).

Rules for PHP variables:

- A variable starts with the \$ sign, followed by the name of the variable
- A variable name must start with a letter or the underscore character
- A variable name cannot start with a number

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

- A variable name can only contain alpha-numeric characters and underscores (A-z, 0-9, and _)
- Variable names are case-sensitive (\$age and \$AGE are two different variables)

Syntax of declaring a variable in PHP is given below:

1. \$variablename=value;

PHP VARIABLE: DECLARING STRING, INTEGER AND FLOAT

- 1. **<?php**
- 2. \$str="hello string";
- 3. x=200;
- 4. \$y=44.6;
- 5. echo "string is: \$str **
**";
- 6. echo "integer is: \$x **
**";
- 7. echo "float is: \$y **\shr/>**";
- 8. **?>**

Output:

string is: hello string

integer is: 200

float is: 44.6

PHP Variable: Sum of two variables

- 1. <?php
- 2. x=5;
- 3. \$y=6;
- 4. z=x+y;
- 5. echo \$z;
- 6. **?>**

Output:

11

PHP Variable: case sensitive

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

In PHP, variable names are case sensitive. So variable name "color" is different from Color, COLOR, COLor etc.

File: variable3.php

- 1. <?php
- 2. \$color="red";
- 3. echo "My car is " . \$color . "**
**";
- 4. echo "My house is " . \$COLOR . "
';
- 5. echo "My boat is " . \$coLOR . "**
**";
- 6. **?>**

Output:

My car is red

Notice: Undefined variable: COLOR in C:\wamp\www\variable.php on line 4

My house is

Notice: Undefined variable: coLOR in C:\wamp\www\variable.php on line 5

My boat is

PHP Variable: Rules

PHP variables must start with letter or underscore only.

PHP variable can't be start with numbers and special symbols.

File: variablevalid.php

- 1. <?php
- 2. \$a="hello";//letter (valid)
- 3. \$_b="hello";//underscore (valid)
- 4.
- 5. echo "\$a **
** \$ b";
- 6. **?>**

Output:

hello

hello

PHP Data Types

PHP data types are used to hold different types of data or values. PHP supports 8 primitive data types that can be categorized further in 3 types:

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

- 1. Scalar Types
- 2. Compound Types
- 3. Special Types

PHP Data Types: Scalar Types

There are 4 scalar data types in PHP.

- 1. boolean
- 2. integer
- 3. float
- 4. string

PHP Data Types: Compound Types

There are 2 compound data types in PHP.

- 1. Array
- 2. Object

PHP Data Types: Special Types

There are 2 special data types in PHP.

- 1. resource
- 2. NULL

PHP Booleans

Booleans are like a switch it has only two possible values either 1 (true) or 0 (false).

Example

<?php

// Assign the value TRUE to a variable

\$show_error = true;

var_dump(\$show_error);

5>

PHP Integers

Integers are whole numbers, without a decimal point (..., -2, -1, 0, 1, 2, ...). Integers can be specified in decimal (base 10), hexadecimal (base 16 - prefixed with 0x) or octal (base 8 - prefixed with 0) notation, optionally preceded by a sign (- or +).

<?php

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

```
$a = 123; // decimal number
var_dump($a);
echo "<br/>";

$b = -123; // a negative number
var_dump($b);
echo "<br/>";

$c = 0x1A; // hexadecimal number
var_dump($c);
echo "<br/>";

$d = 0123; // octal number
var_dump($d);
?>
```

PHP Floating Point Numbers or Doubles

Floating point numbers (also known as "floats", "doubles", or "real numbers") are decimal or fractional numbers, like demonstrated in the example below.

Example

```
<?php
$a = 1.234;
var_dump($a);
echo "<br/>;
$b = 10.2e3;
var_dump($b);
echo "<br/>;
$c = 4E-10;
var_dump($c);
p>
```

PHP Strings

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

Strings are sequences of characters, where every character is the same as a byte.

A string can hold letters, numbers, and special characters and it can be as large as up to 2GB (2147483647 bytes maximum). The simplest way to specify a string is to enclose it in single quotes (e.g. 'Hello world!'), however you can also use double quotes ("Hello world!").

Example

```
<Pphp
$a = 'Hello world!';
echo $a;
echo "<br>";

$b = "Hello world!";
echo $b;
echo "<br>";

$c = 'Stay here, I\'ll be back.';
echo $c;
p>
```

PHP Arrays

An array is a variable that can hold more than one value at a time. It is useful to aggregate a series of related items together, for example a set of country or city names.

An array is formally defined as an indexed collection of data values. Each index (also known as the key) of an array is unique and references a corresponding value.

Example

```
<Pphp
$colors = array("Red", "Green", "Blue");
var_dump($colors);
echo "<br/>br>";
$color_codes = array(
   "Red" => "#ff0000",
   "Green" => "#00ff00",
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

```
"Blue" => "#0000ff"
);
var_dump($color_codes);
>>
```

PHP Objects

An object is a data type that not only allows storing data but also information on, how to process that data. An object is a specific instance of a class which serve as templates for objects. Objects are created based on this template via the new keyword.

Every object has properties and methods corresponding to those of its parent class. Every object instance is completely independent, with its own properties and methods, and can thus be manipulated independently of other objects of the same class.

Here's a simple example of a class definition followed by the object creation.

Example

```
<Pphp
// Class definition
class greeting{
    // properties
    public $str = "Hello World!";
    // methods
    function show_greeting(){
        return $this->str;
    }
}
// Create object from class
$message = new greeting;
var_dump($message);
p>
```

Tip: The data elements stored within an object are referred to as its properties and the information, or code which describing how to process the data is called the methods of the object.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

PHP Resources

A resource is a special variable, holding a reference to an external resource.

Resource variables typically hold special handlers to opened files and database connections.

Example

```
<?php
// Open a file for reading
$handle = fopen("note.txt", "r");
var_dump($handle);
echo "<br/>";

// Connect to MySQL database server with default setting
$link = mysql_connect("localhost", "root", "");
var_dump($link);
p>
```

PHP NULL

The special NULL value is used to represent empty variables in PHP. A variable of type NULL is a variable without any data. NULL is the only possible value of type null.

Example

```
<Pphp
$a = NULL;
var_dump($a);
echo "<br/>br>";

$b = "Hello World!";
$b = NULL;
var_dump($b);
p>
```

When a variable is created without a value in PHP like \$var; it is automatically assigned a value of null. Many novice PHP developers mistakenly considered both \$var1 = NULL; and \$var2 =

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

""; are same, but this is not true. Both variables are different — the \$var1 has null value while \$var2 indicates no value assigned to it.

PHP Variables Scope

In PHP, variables can be declared anywhere in the script.

The scope of a variable is the part of the script where the variable can be referenced/used.

PHP has three different variable scopes:

- local
- global
- static

Global and Local Scope

A variable declared outside a function has a GLOBAL SCOPE and can only be accessed outside a function:

```
Example
<pphp
$x = 5; // global scope

function myTest() {
    // using x inside this function will generate an error
    echo "<p>Variable x inside function is: $x";
}
myTest();

echo "Variable x outside function is: $x";
?>
```

A variable declared **within** a function has a LOCAL SCOPE and can only be accessed within that function:

```
<Pphp
function myTest() {
    $x = 5; // local scope</pre>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

```
echo "Variable x inside function is: $x";
}
myTest();

// using x outside the function will generate an error echo "Variable x outside function is: $x";

?>
```

PHP The global Keyword

The global keyword is used to access a global variable from within a function.

To do this, use the global keyword before the variables (inside the function):

Example

```
<Pphp
$x = 5;
$y = 10;
function myTest() {
    global $x, $y;
    $y = $x + $y;
}
myTest();
echo $y; // outputs 15
P>
```

PHP also stores all global variables in an array called \$GLOBALS[index]. The index holds the name of the variable. This array is also accessible from within functions and can be used to update global variables directly.

The example above can be rewritten like this:

Example

<php</pre>

x = 5;

\$y = 10;

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

```
function myTest() {
    $GLOBALS['y'] = $GLOBALS['x'] + $GLOBALS['y'];
}
myTest();
echo $y; // outputs 15
p>
```

PHP The static Keyword

Normally, when a function is completed/executed, all of its variables are deleted. However, sometimes we want a local variable NOT to be deleted. We need it for a further job.

To do this, use the static keyword when you first declare the variable:

Example

```
<Pphp
function myTest() {
   static $x = 0;
   echo $x;
   $x++;
}

myTest();
myTest();</pre>
```

PHP Operators

myTest();

5>

Operators are used to perform operations on variables and values.

PHP divides the operators in the following groups:

- > Arithmetic operators
- > Assignment operators
- Comparison operators
- ➤ Increment/Decrement operators
- Logical operators

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

- String operators
- > Array operators

PHP Arithmetic Operators

The PHP arithmetic operators are used with numeric values to perform common arithmetical operations, such as addition, subtraction, multiplication etc.

| Operator | Name | Example | Result |
|----------|----------------|------------|---|
| + | Addition | \$x + \$y | Sum of \$x and \$y |
| - | Subtraction | \$x - \$y | Difference of \$x and \$y |
| * | Multiplication | \$x * \$y | Product of \$x and \$y |
| / | Division | \$x / \$y | Quotient of \$x and \$y |
| % | Modulus | \$x % \$y | Remainder of \$x divided by \$y |
| ** | Exponentiation | \$x ** \$y | Result of raising \$x to the \$y'th power (Introduced in PHP 5.6) |

Example Program

```
<?php
  // variable 1
$x = 29;
  // variable 2
$y = 4;
  // some arithmetic operations on
// these two variables
echo ($x + $y), "\n";
echo($x - $y), "\n";
echo($x * $y), "\n";
echo($x / $y), "\n";
echo($x % $y), "\n";</pre>
```

PHP Assignment Operators

5>

The PHP assignment operators are used with numeric values to write a value to a variable.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

The basic assignment operator in PHP is "=". It means that the left operand gets set to the valu of the assignment expression on the right.

| Assignment | Same as | Description | |
|------------|-----------|---|--|
| X = A | X = A | The left operand gets set to the value of the expression on the right | |
| x += y | x = x + y | Addition | |
| x -= y | x = x - y | Subtraction | |
| x *= y | X = X * y | Multiplication | |
| x /= y | x = x / y | Division | |
| x %= y | x = x % y | Modulus | |

Example Program

```
<pphp</pre>
// simple assign operator
y = 75;
echo $y, "\n";
// add then assign operator
y = 100;
y = 200;
echo $y, "\n";
// subtract then assign operator
\$y = 70;
y = 10;
echo $y, "\n";
// multiply then assign operator
y = 30;
y = 20;
echo $y, "\n";
// Divide then assign(quotient) operator
y = 100;
y = 5;
echo $y, "\n";
// Divide then assign(remainder) operator
y = 50;
y \% = 5;
echo $y;
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

PHP Comparison Operators

The PHP comparison operators are used to compare two values (number or string):

| Operator | Name | Example | Result |
|--|--------------------------|-------------|---|
| == | Equal | \$x == \$y | Returns true if \$x is equal to \$y |
| | Identical | \$x === \$y | Returns true if \$x is equal to \$y, and they are of the same type |
| != | Not equal | \$x != \$y | Returns true if \$x is not equal to \$y |
| <> − ← ← ← ← ← ← ← ← ← ← ← ← ← ← ← ← ← ← | Not equal | \$x <> \$y | Returns true if \$x is not equal to \$y |
| !== | Not identical | \$x !== \$y | Returns true if \$x is not equal to \$y, or they are not of the same type |
| > | Greater than | \$x > \$y | Returns true if \$x is greater than \$y |
| < | Less than | \$x < \$y | Returns true if \$x is less than \$y |
| >= | Greater than or equal to | \$x >= \$y | Returns true if \$x is greater than or equal to \$y |
| < = | Less than or | \$x <= \$y | Returns true if \$x is less than or equal |

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

```
Example Program
```

```
<?php
$a = 80;
b = 50;
c = 80;
// Here var_dump function has been used to
// display structured information. We will learn
// about this function in complete details in further
// articles.
var_dump(a == c) + "\n";
var_dump(a != b) + "\n";
var_dump(a \le b) + \n";
var_dump(a === c) + 'n';
var_dump($a !== $c) + "\n";
var_dump(a < b) + "\n";
var_dump(a > b) + "\n";
var_dump(a \le b) + \n";
var_dump(a >= b);
 5>
```

PHP Increment / Decrement Operators

The PHP increment operators are used to increment a variable's value.

The PHP decrement operators are used to decrement a variable's value.

| Operator | Name | Description | |
|----------|----------------|---|--|
| ++\$x | Pre-increment | Increments \$x by one, then returns \$x | |
| \$x++ | Post-increment | Returns \$x, then increments \$x by one | |
| \$x | Pre-decrement | Decrements \$x by one, then returns \$x | |
| \$x | Post-decrement | Returns \$x, then decrements \$x by one | |

Example Program

```
$\text{?php}
$x = 2;
echo ++$x, " First increments then prints \n";
echo $x, "\n";
$x = 2;
echo $x++, " First prints then increments \n";
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

```
echo $x, "\n";

$x = 2;
echo -$x, " First decrements then prints \n";
echo $x, "\n";

$x = 2;
echo $x--, " First prints then decrements \n";
echo $x;
```

PHP Logical Operators

The PHP logical operators are used to combine conditional statements.

| Operator | Name | Example | Result |
|----------|------|-------------|---|
| and | And | \$x and \$y | True if both \$x and \$y are true |
| or | Or | \$x or \$y | True if either \$x or \$y is true |
| xor | Xor | \$x xor \$y | True if either \$x or \$y is true, but not both |
| && | And | \$x && \$y | True if both \$x and \$y are true |
| П | Or | \$x \$y | True if either \$x or \$y is true |
| ! | Not | !\$x | True if \$x is not true |

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

Example Program

```
<?php
 x = 50;
y = 30;
 if (\$x == 50 \text{ and } \$y == 30)
  echo "and Success \n";
 if (\$x == 50 \text{ or } \$y == 20)
  echo "or Success \n";
if (\$x == 50 \text{ xor } \$v == 20)
  echo "xor Success \n";
 if (\$x == 50 \&\& \$y == 30)
  echo "&& Success \n";
 if (\$x == 50 \mid \$y == 20)
  echo " | Success \n";
 if (!$z)
  echo "! Success \n";
 ?>
```

PHP String Operators

PHP has two operators that are specially designed for strings.

| Operator | Name | Example | Result |
|----------|--------------------------|------------------|------------------------------------|
| | Concatenation | \$txt1.\$txt2 | Concatenation of \$txt1 and \$txt2 |
| .= | Concatenation assignment | \$txt1 .= \$txt2 | Appends \$txt2 to \$txt1 |

Example Program

<?php

```
$x = "Geeks";

$y = "for";

$z = "Geeks!!!";

echo $x . $y . $z, "\n";

$x .= $y . $z;

echo $x;

>>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

PHP Array Operators

The PHP array operators are used to compare arrays.

| Operator | Name | Example | Result |
|----------|--------------|-------------|---|
| + | Union | \$x + \$y | Union of \$x and \$y |
| == | Equality | \$x == \$y | Returns true if \$x and \$y have the same key/value pairs |
| === | Identity | \$x === \$y | Returns true if \$x and \$y have the same key/value pairs in the same order and of the same types |
| != | Inequality | \$x != \$y | Returns true if \$x is not equal to \$y |
| <> | Inequality | \$x <> \$y | Returns true if \$x is not equal to \$y |
| !== | Non-identity | \$x !== \$y | Returns true if \$x is not identical to \$y |

Example Program

```
<Pphp
$x = array("k" => "Car", "l" => "Bike");
$y = array("a" => "Train", "b" => "Plane");
var_dump($x + $y);
var_dump($x == $y) + "\n";
var_dump($x != $y) + "\n";
var_dump($x <> $y) + "\n";
var_dump($x === $y) + "\n";
var_dump($x !== $y) + "\n";
```

Conditional or Ternary Operators

These operators are used to compare two values and take either of the result simultaneously, depending on whether the outcome is TRUE or FALSE. These are also used as shorthand notation for if...else statement that we will read in the article on decision making. Syntax:

```
$var = (condition)? value1 : value2;
```

Here, condition will either evaluate to true or false. If the condition evaluates to True, then value1 will be assigned to the variable \$var otherwise value2 will be assigned to it.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

| Operator | Name | Operation |
|----------|---------|---|
| P: | Ternary | If condition is true? then \$x : or else \$y. This means that if condition is true then left result of the colon is accepted otherwise the result on right. |

Example Program

<?php</p>

x = -12;

echo (x > 0)? 'The number is positive': 'The number is negative';

5>

PHP operator Precedence and associativity

An *expression* is a bit of PHP that can be evaluated to produce a value. The simplest expressions are literal values and variables. A literal value evaluates to itself, while a variable evaluates to the value stored in the variable. More complex expressions can be formed using simple expressions and operators.

An *operator* takes some values (the operands) and does something (for instance, adds them together). Operators are written as punctuation symbols—for instance, the + and - familiar to us from math. Some operators modify their operands, while most do not.

<u>Table</u> summarizes the operators in PHP, many of which were borrowed from C and Perl. The column labeled "P" gives the operator's precedence; the operators are listed in precedence order, from highest to lowest. The column labeled "A" gives the operator's associativity, which can be L (left-to-right), R (right-to-left), or N (non-associative).

PHP operators

| P | A | Operator | Operation |
|----|---|----------|-------------------|
| 19 | N | new | Create new object |
| 18 | R | [| Array subscript |
| 17 | R | ! | Logical NOT |
| | R | ~ | Bitwise NOT |

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

| | R | ++ | Increment |
|----|---|---|-------------------------------------|
| | R | | Decrement |
| | R | (int), (double), (string), (array), (ob ject) | Cast |
| | R | @ | Inhibit errors |
| 16 | L | * | Multiplication |
| | L | / | Division |
| | L | % | Modulus |
| 15 | L | + | Addition |
| | L | - | Subtraction |
| | L | · | String concatenation |
| 14 | L | << | Bitwise shift left |
| | L | >> | Bitwise shift right |
| 13 | N | <, <= | Less than, less than or equal |
| | N | >,>= | Greater than, greater than or equal |
| 12 | N | == | Value equality |
| | N | !=, <> | Inequality |
| | N | === | Type and value equality |
| | N | !== | Type and value inequality |
| 11 | L | & | Bitwise AND |
| 10 | L | ^ | Bitwise XOR |
| 9 | L | I | Bitwise OR |
| 8 | L | && | Logical AND |
| 7 | L | II | Logical OR |

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

| 6 | L | P: | Conditional operator |
|---|---|---|---------------------------|
| 5 | L | = | Assignment |
| | L | +=, -=, *=, /=, .=, %=, &=,
 =, ^=, ~=, <<=, >>= | Assignment with operation |
| 4 | L | and | Logical AND |
| 3 | L | xor | Logical XOR |
| 2 | L | or | Logical OR |
| 1 | L | , | List separator |

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: I (Introduction to PHP) BATCH-2017-2020

POSSIBLE QUESTIONS

Part B (2 Marks)

- 1. What is PHP?
- 2. What are the tools required for PHP Programming?
- 3. Write the syntax of PHP?
- 4. What are the differences between echo and print in PHP?
- 5. What is the use of "echo" in php?

Part C (6 Marks)

- 1. Discuss about PHP inventions and versions.
- 2. How to declare a variable in PHP? What are the rules to be followed to declare the variable?
- 3. What is Operator? Explain the operators in PHP with examples.
- 4. Explain on different types of PHP variables.
- 5. Illustrate the Pros and Cons of PHP.

Department of Information Technology

III B.Sc(IT)

(BATCH 2017-2020)

VI SEMESTER

PHP PROGRAMMING (17ITU601A)

PART-A OBJECTIVE TYPE/ MULTIPLE CHOICE QUESTIONS

UNIT I

| S.NO | QUESTIONS | OPT 1 | OPT 2 | OPT 3 | OPT 4 | ANSWER |
|------|---|------------------|------------------|--------------|-----------------|-----------------|
| 1 | what does PHP stand for? i) Personal Home Page ii) Hypertext Preprocessor iii) Pretext Hypertext Processor iv) Preprocessor Home Page | Both i) and iii) | Both ii) and iv) | Only ii) | Both i) and ii) | Both i) and ii) |
| 2 | Who is known as the father of PHP? | Rasmus Lerdorf | Willam Makepiece | Drek Kolkevi | List Barely | Rasmus Lerdorf |
| 3 | PHP is an example of scripting language | Server-side | Client-side | Browser-side | In-side | Server-side |
| 4 | PHP files have a default file extension of | .html | .xml | .php | .ph | .php |
| 5 | <pre>what will be the output of the following PHP code ? < ?php echo \$red; ?></pre> | 0 | Nothing | True | Error | Nothing |
| 6 | PHP scripts are enclosed within | <php> </php> | php ? | ?php ?php |) | php ? |
| 7 | Which of the following variables is not a predefined variable? | \$get | \$ask | \$request | \$post | \$ask |
| 8 | Which of the below symbols is a newline character? | \r | \n | /n | /r | \n |
| 9 | If \$a = 12 what will be returned when (\$a == 12) ? 5 : 1 is executed? | 12 | 1 | Error | 5 | 5 |

| 10 | What will be the output of the following PHP code? < ?php Echo "Hello world I am learning PHP"; | Hello world | Hello world I am | Hello world I
am learning | Error | Hello world I am |
|----|---|--------------------|------------------|------------------------------|-------------------|-------------------|
| | ?> | | learning PHP | PHP | | learning PHP |
| 11 | What will be the output of the following PHP code? php \$a = 10; echo ++\$a; echo \$a++; echo \$a; echo ++\$a; ? | 11111213 | 11121213 | 11111212 | 11111112 | 11111213 |
| 12 | A PHP script should start with and end with | < php > | < ? php ?> | ? | php ? | ? |
| 13 | Which of the following is/are a PHP code editor? i) Notepad ii) Notepad++ iii) Adobe Dreamweaver iv) PDT | Only iv) | all | i), ii) and iii) | Only iii) | all |
| 14 | which of the following must be installed on your computer so as to run PHP script? i) Adobe Dreamweaver ii) PHP iii) Apache iv) IIS | ll of the mentione | Only ii) | ii) and iii) | ii), iii) and iv) | ii), iii) and iv) |
| 15 | Which version of PHP introduced Try/catch Exception? | PHP 4 | PHP 5 | PHP 5.3 | PHP 6 | PHP 5 |

| 16 | We can use to comment a single line? i) /? ii) // iii) # iv) /* */ | Only ii) | i), iii) and iv) | ii), iii) and iv) | Both ii) and iv) | ii), iii) and iv) |
|----|--|------------|------------------|-------------------|------------------|-------------------|
| 17 | What will be the output of the following php code? php \$num = 1; \$num1 = 2; print \$num . "+". \$num1; ? | 3 | 1+2 | 1.+.2 | Error | 1+2 |
| 18 | What will be the output of the following php code? php \$num = "1"; \$num1 = "2"; print \$num+\$num1; ? | 3 | 1+2 | 1.+.2 | Error | 3 |
| 19 | Which of following variables can be assigned a value to it? i) \$3hello ii) \$_hello iii) \$this iv) \$This | ALL | Only ii) | ii), iii) and iv) | ii) and iv) | ii) and iv) |
| 20 | Which of the following PHP statements will output Hello World on the screen? i) echo ("Hello World"); ii) print ("Hello World"); iii) printf ("Hello World"); iv) sprintf ("Hello World"); | i) and ii) | i), ii) and iii) | ALL | i), ii) and iv) | i), ii) and iii) |

| 21 | What will be the output of the following PHP code? php \$color = "maroon"; \$var = \$color[2]; echo "\$var"; ? | a | Error | \$var | r | r |
|----|--|-------------------|---------------------|------------------|------------------|------------------|
| | | PHP can be used | PHP makes a | PHP | PHP can not be | PHP can not be |
| 22 | Which of the following is not true? | to develop web | | applications can | embedded into | embedded into |
| | | applications. | website dynamic | not be compile | html. | html. |
| 23 | In PHP language PEAR stands for | A PHP | PHP Event and | PHP Extension | None of these | PHP Extension |
| | | Enhancement | Application | and Application | above | and Application |
| 24 | PHP does not have an built in support for which one of the following? | JPEG | GIF | MPEG | PDF | MPEG |
| 25 | PHP configuration settings are maintained in | A pws- | D. ch. dat | had and an of | | ala a tat |
| 25 | | php5cgi.reg | B php.ini | httpd.conf | D httpd-info.con | php.ini |
| 26 | During PHP installation which function creates a HTML page to display records how PHP was installed? | phpconf() | phpinfo() | phprec() | phpdisplay() | phpinfo() |
| | Select the incorrect statement about PHP programming | Classes are case- | Functions rae case- | Variables are | Constants are | Variables are |
| 27 | language | insensitive | insensitive | case-insensitive | case-sensitive | case-insensitive |
| 28 | In PHP programming literal is a | Class | Function | Data value | None | Data value |
| 29 | Which class name is reserveed in PHP? | stdClass | nameClass | newClass | None | stdClass |
| 30 | When you need to obtain the ASCII value of a character which of the following function you apply in PHP? | chr(); | asc(); | ord(); | val(); | ord(); |

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

UNIT-II

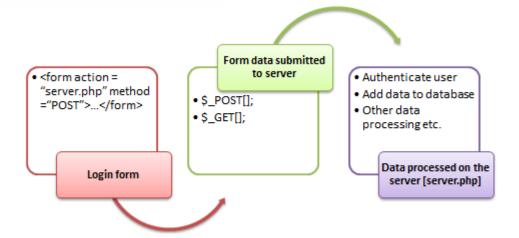

Handling HTML form with PHP:

Capturing Form Data -GET and POST form methods- Dealing with multi value fields -Redirecting a form after submission -PHP conditional events and Loops: PHP IF Else conditional statements (Nested IF and Else) -Switch case, while ,For and Do While Loop -Goto , Break ,Continue and exit

Capturing Form Data

Form

Forms are used to get input from the user and submit it to the web server for processing. The diagram below illustrates the form handling process.

A form is an HTML tag that contains graphical user interface items such as input box, check boxes radio buttons etc.

The form is defined using the <form>...</form> tags and GUI items are defined using form elements such as input.

Use of Forms

- Forms come in handy when developing flexible and dynamic applications that accept user input.
- Forms can be used to edit already existing data from the database

Example

All Web forms start with an opening <form> tag, and end with a closing </form> tag: <form action="myscript.php" method="POST">

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

<!-- Contents of the form go here -->

</form>

Form attributes

There are two attributes within the opening \form> tag:

action - tells the browser where to send the form data. This should either be an absolute URL or a relative URL.

method - tells the browser how to send the form data. You can use two methods: GET is for sending small amounts of data and makes it easy for the user to resubmit the form, and POST can send much larger amounts of form data.

PHP Form Text Field

A text input field allows the user to enter a single line of text.

Value attribute

We can optionally prefill the field with an initial value using the value attribute. To leave it blank, specify an empty string for the value attribute, or leave the attribute out altogether.

<label for="textField">A text input field</label>

sinput type="text" name="textField" id="textField" value="" />

Example

The following code is for index.htm file and it has a text field and submit button.

<html>

<body>

</html>

Name the following script as index.php and put it into the same folder as above index.htm file. It accepts the value from the text field by using field name user.

```
<Pphp
print "Welcome <b>" . $_GET ['user'] . "</b><br/>";
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

5>

PHP Form Textarea

A text area field is similar to a text input field, but it allows the user to enter multiple lines of text.

Unlike most other controls, an initial value is placed between the <textarea> ... </textarea> tags, rather than in a value attribute.

A textarea element must include attributes for the height of the control in rows (rows) and the width of the control in columns (cols):

<label for="textAreaField">A text area field</label>

<textarea name="textAreaField" id="textAreaField" rows="4" cols="50"></textarea>

Example

Name the following script as index.htm. It has a text area and a submit button.

PHP Form Check Box

A checkbox field is a simple toggle button. It can be either on or off.

The value attribute should contain the value that will be sent to the server when the checkbox is selected. If the checkbox isn't selected, nothing is sent.

<label for="checkboxField">A checkbox field</label>

sinput type="checkbox" name="checkboxField" id="checkboxField" value="yes" />

You can preselect a checkbox by adding the attribute checked="checked" to the input tag:

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

sinput type="checkbox" checked="checked" ... />.

By creating multiple checkbox fields with the same name attribute, you can allow the user to select multiple values for the same field.

```
Example
The following script is for index.htm. It has several checkboxes.
<html>
<body>
<form action ="index.php">
<input type ="checkbox" name ="chkFries" value ="11.00">Fries
 input type = "checkbox" name = "chkSoda" value = "12.85" > Soda 
 <ii>\sinput type = "checkbox" name = "chkShake" value = "1.30" \shake \shake \li></ii>
 <input type ="checkbox" name ="chkKetchup" value =".05">Ketchup
<input type ="submit">
</form>
</body>
</html>
The following code is for index.php and it accepts the value from the checkboxes.
<?PHP
print "chkFries:" . $chkFries . "<br/>";
print "chkSoda:" $chkSoda . "<br/>";
print "chkShake:" . $chkShake . "<br/>";
print "chkKetchup" . $chkKetchup . "<br/>>";
\text{stotal} = 0;
if (!empty($chkFries)){
 print ("You chose Fries <br>");
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

```
$total = $total + $chkFries;
}

if (!empty($chkSoda)){
  print ("You chose Soda <br>");
  $total = $total + $chkSoda;
}

if (!empty($chkShake)){
  print ("You chose Shake <br>");
  $total = $total + $chkShake;
}

if (!empty($chkKetchup)){
  print ("You chose Ketchup <br>");
  $total = $total + $chkKetchup;
}

print "The total cost is \$$total";
```

P>

PHP Form Select

Form Select as Pull-down menu

A pull-down menu allows users to choose a single item from a predefined list of options. The size attribute's value of 1 tells the browser that you want the list to be in a pull-down menu format.

Within the select element, you create an option element for each of your options.

Place the option label between the <option> ... </option> tags.

Each option element can have an optional value attribute, which is the value sent to the server if that option is selected.

If you don't include a value attribute, the text between the <option> ... </option> tags is sent instead: <label for="pullDownMenu">A pull-down menu</label>

<select name="pullDownMenu" id="pullDownMenu" size="1">

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

<option value="option1">Option 1</option>
<option value="option2">Option 2</option>
<option value="option3">Option 3</option>
</select>

Form Select as List Box

A list box works like a pull-down menu, except that it displays several options at once.

To turn a pull-down menu into a list box, change the size attribute from 1 to the number of options to display at once:

Form Select as multi-select list box

A multi-select list box allows the user to select multiple items at once by holding down Ctrl or Command key.

To turn a normal list box into a multi-select box, add the attribute multiple with a value of "multiple" to the select element.

If the user selects more than one option, all the selected values are sent to the server:

<label for="multiListBox">A multi-select list box</label>

<select name="multiListBox" id="multiListBox" size="3" multiple="multiple">

<option value="option1">Option 1

<option value="option2">Option 2</option>

<option value="option3">Option 3</option>

</select>

We can preselect an option in any type of select element by adding the attribute selected="selected" to the relevant <option> tag - for example: <option value="option1" selected="selected">.

Example

Name the following script as index.php. It has a multi-select list box.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

```
<html>
<body>
<div>
<form action="index.php" method="post">
<select name="products[]" multiple="multiple">
 <option>A</option>
 <option>B</option>
 <option>C</option>
 <option>D</option>
</select>
<input type="submit" value="hit it!" />
</form>
</div>
</body>
</html>
The following script is for index.php.
<?php/*from ww w . j ava 2 s . c o m*/</pre>
 if (is_array ( $_POST ['products'] )) {
  print "Your product choices are:";
  print "";
  foreach ( $_POST ['products'] as $value ) {
   print "$value\n";
  print "";
5>
```

PHP Form RadioButton

The radio buttons are for single choice from multiple options. All radio buttons in the group have the same name attribute.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Only one button can be selected per group. As with checkboxes, use the value attribute to store the value that is sent to the server if the button is selected.

The value attribute is mandatory for checkboxes and radio buttons, and optional for other field types.

```
<label for="radioButtonField1">A radio button field</label>
<input type="radio" name="radioButtonField" id="radioButtonField1" value="radio1" />
<label for="radioButtonField2">Another radio button</label>
<input type="radio" name="radioButtonField" id="radioButtonField2" value="radio2" />
We can preselect a radio button using the same technique as for preselecting checkboxes.
```

Example

The following script is for index.htm. It has a group of radio buttons.

The following script is for index.php. It reads the data from the form above.

```
<Pphp
$color = $_POST['color'];
if( ( $color != null ) )
{
    $msg .= "a nice $color ";</pre>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

```
echo($msg);
 }
2>
PHP Form Hidden Field
A hidden field is not displayed on the page.
It simply stores the text value specified in the value attribute.
Hidden fields are great for passing additional information from the form to the server.
<label for="hiddenField">A hidden field</label>
<input type="hidden" name="hiddenField" id="hiddenField" value="" />
Example
The following form uses hidden field to store number of tries.
php
 \sum_{\text{guess}} 42;
 message = "";
 if (! isset ( $_POST ['guess'] )) {
  $message = "Welcome!";
 } else if ($_POST ['guess'] > $num_to_guess) {
  $message = $_POST ['guess'] . " is too big!";
 } else if ($_POST ['guess'] < $num_to_guess) {</pre>
  $message = $_POST ['guess'] . " is too small!";
 } else {
  $message = "Well done!";
 $guess = (int) $ POST ['guess'];
 $num_tries = ( int ) $_POST ['num_tries'];
 $num_tries ++;
 5>
<html>
<body>
<?php print $message?>
Guess number: <?php print $num_tries?><br/>>
```

<form method="post" action="<?php</pre>

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

print \$_SERVER ['PHP_SELF']?>">
<input type="hidden" name="num_tries"
 value="<?php
 print \$num_tries?>" /> Type your guess here: <input type="text" name="guess" value="<?php
 print \$guess?>" />
</form>
</body>
</html>

PHP Form Validation

Basic input validation in PHP is done using the following functions.

is_string(),
is_numeric(),
is_float(),
is_array(), and
is_object().

Each of these functions take a variable and return true if that variable is of the appropriate type.

The three basic validation checks we should do.

- whether we have required variables,
- whether the variables have a value assigned, and
- whether they have the type we are expecting.

After the basic check, we can do more check, such as integer value range, the string length, count of array elements, etc.

CTYPE functions

There are eleven CTYPE functions in total. they work in the same way as is_numeric().

Function	Meaning
ctype_alnum()	Matches A?Z, a?z, 0?9
ctype_alpha()	Matches A?Z, a?z

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Function	Meaning
ctype_cntrl()	Matches ASCII control characters
ctype_digit()	Matches 0?9
ctype_graph()	Matches values that can be represented graphically
ctype_lower()	Matches a?z
ctype_print()	Matches visible characters (not whitespace)
ctype_punct()	Matches all non-alphanumeric characters (not whitespace)
ctype_space()	Matches whitespace (space, tab, new line, etc.)
ctype_upper()	Matches A?Z
ctype_xdigit()	Matches digits in hexadecimal format

<?PHP

\$var = "123456789a";
print (int)ctype_digit(\$var);
?>

Example

The following code checks whether the \$Age variable has a numeric value between 18 and 30.

```
if (isset($Age)) {
    if (is_numeric($Age)) {
        if (($Age > 18) && ($Age < 30)) {
            print " input is valid";
        }
}</pre>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

PHP Form File Upload

A file select field allows the users to choose a file on their hard drive for uploading to the server. The value attribute is usually ignored by the browser:

```
<label for="fileSelectField">A file select field</label>
<input type="file" name="fileSelectField" id="fileSelectField" value="" />
Information
```

PHP creates a superglobal array called \$_FILES containing various pieces of information about the file or files.

Each file is described by an element in the \$_FILES array keyed on the name of the field that was used to upload the file.

For example, say your form contained a file select field called photo:

```
<input type="file" name="photo" value="" />
```

If the user uploaded a file using this field, its details would be accessible via the following PHP array element:

\$_FILES["photo"]

This array element is itself an associative array that contains information about the file. For example, you can find out the uploaded file 's filename like this:

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Fields of file information

Here's a full list of the elements stored in each nested array within the \$_FILES array:

Array	
Element	Description
name	The filename of the uploaded file.
type	The MIME type of the uploaded file. For example, a JPEG image would
	probably have a MIME type of image/jpeg , whereas a QuickTime
	movie file would have a MIME type of video/quicktime.
size	The size of the uploaded file, in bytes.
tmp_name	The full path to the temporary file on the server that contains the
	uploaded file.
error	The error or status code associated with the file upload.

Error

Error element contains an integer value that corresponds to a built-in constant that explains the error.

Possible values include:

Constant	Value	Meaning
UPLOAD_ERR_OK	0	The file was uploaded successfully.
UPLOAD_ERR_INI_SIZE	1	The file is bigger than the allowed file size specified in the upload_max_filesize directive in the php.ini file.
UPLOAD_ERR_FORM_SIZE	2	The file is bigger than the allowed file size specified in the MAX_FILE_SIZE

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Constant	Value	Meaning
		directive in the form.
UPLOAD_ERR_NO_FILE	4	No file was uploaded.
UPLOAD_ERR_NO_TMP_DIR	6	PHP doesn 't have access to a temporary folder on the server to store the file.
UPLOAD_ERR_CANT_WRITE	7	The file couldn 't be written to the server 's hard disk for some reason.
UPLOAD_ERR_EXTENSION	8	The file upload was stopped by one of the currently loaded PHP extensions.

\$filename = \$_FILES["photo"]["name"];

File Size

PHP allows you to limit the size of uploaded files.

First, you can add or edit a directive called upload_max_filesize in the php.ini file:

; Maximum allowed size for uploaded files.

upload_max_filesize = 32M

If a user tries to upload a file larger than this value (32 megabytes in this example), the file upload is cancelled and the corresponding error array element is set to UPLOAD_ERR_INI_SIZE.

Second, you can add a hidden form field called MAX_FILE_SIZE that specifies the maximum allowed size in bytes of an uploaded file. This should be placed before the file upload field:

<input type="hidden" name="MAX_FILE_SIZE" value="10000" />
<input type="file" name="fileSelectField" id="fileSelectField" value="" />

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

If the uploaded file is larger than this figure, the upload is cancelled and the corresponding error array element is set to UPLOAD_ERR_FORM_SIZE.

We can check the size of an uploaded file manually and reject it if it's too large:

```
if ($_FILES["photo"]["size"]> 10000) die("File too big!");
```

Move an Uploaded File

The uploaded file is automatically stored in a temporary folder on the server. To use the file, you need to move it out of the temporary folder using PHP's move_uploaded_file() function.

move_uploaded_file() function takes two arguments: the path of the file to move, and the path to move it to.

You can determine the existing path of the file using the tmp_name array element of the nested array inside the \$_FILES array.

move_uploaded_file() returns true if the file was moved successfully, or false if there was an error (such as the path to the file being incorrect).

Here's an example:

```
if ( move_uploaded_file( $_FILES["photo"]["tmp_name"], "/home/matt/photos/photo.jpg" ) ) {
   echo "Your file was successfully uploaded.";
} else {
   echo "There was a problem uploading your file - please try again.";
}
```

Example

Here is an example HTML form that allows users to select a file for uploading to your server.

```
<form enctype="multipart/form-data" method="post" action="upload.php">
```

```
Send this file: <input name="userfile" type="file" /><br />
<input type="submit" value="Send File" />
</form>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

We give the new file element the name userfile.

If there are file uploads, PHP puts information in the superglobal \$_FILES for each one in the form of an array. If you run var_dump() on \$_FILES.

```
<?PHP
```

```
$filename = $_FILES['userfile']['name'];
$filesize = $_FILES['userfile']['size'];
print "Received $filename - its size is $filesize";
}>
```

If you find files over a certain size aren't being uploaded properly, you may need to increase the upload_max_filesize setting in your php.ini file.

Example

To uploaded files using move_uploaded_file() function.

The first parameter is the name of the uploaded file. This corresponds to \$_FILES['userfile']['tmp_name']. The second parameter is the target file path name.

If all goes well, PHP returns true, and the file will be where you expect it.

Here is the whole operation in action:

```
if (move_uploaded_file($_FILES['userfile']['tmp_name'], "/place/for/file"))
{
    print "Received {$_FILES['userfile']['name']} - its size is {$_FILES['userfile']['size']}";
} else {
    print "Upload failed!";
}
```

Example

The move_uploaded_file() function is the same as the rename() function, plus it checks if the file was just uploaded by the PHP script.

To perform this check yourself, use the is_uploaded_file() function. It returns true if the file was uploaded by the script and false if not.

Here is a simple example:

```
if (is uploaded file($somefile)) {
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

```
copy($somefile, "/var/www/userfiles/$somefile");
}
Example 4
A File Upload Script
    <html>
     <body>
    <?php
    if ( isset( $_POST["sendPhoto"] ) ) {
     processForm();
    } else {
     displayForm();
    function processForm() {
     if (isset($_FILES["photo"]) and $_FILES["photo"]["error"] == UPLOAD_ERR_OK) {
      if ( $_FILES["photo"]["type"] != "image/jpeg" ) {
       echo "JPEG photos only, thanks!";
      } elseif ( !move_uploaded_file( $_FILES["photo"]["tmp_name"], "photos/" . basename(
$_FILES["photo"]["name"] ) ) ) {
       echo "Sorry, there was a problem uploading that photo." . $_FILES["photo"]["error"]
      } else {
       displayThanks();
      }
     } else {
      switch( $_FILES["photo"]["error"] ) {
       case UPLOAD_ERR_INI_SIZE:
         $message = "The photo is larger than the server allows.";
         break;
       case UPLOAD_ERR_FORM_SIZE:
         $message = "The photo is larger than the script allows.";
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

```
break;
     case UPLOAD_ERR_NO_FILE:
      $message = "No file was uploaded. Make sure you choose a file to upload.";
      break;
     default:
      $message = "Please contact your server administrator for help.";
   }
   echo "Sorry, there was a problem uploading that photo. $\square$message";
}
}
function displayForm() {
2>
  Please enter your name and choose a photo to upload, then click
Send Photo.
  <form action="photo_upload.php" method="post" enctype="multipart/form-data">
    sinput type="hidden" name="MAX_FILE_SIZE" value="50000" />
    <label for="visitorName">Your name</label>
    sinput type="text" name="visitorName" id="visitorName" value="" />
    <label for="photo">Your photo</label>
    <input type="file" name="photo" id="photo" value=""" />
    sinput type="submit" name="sendPhoto" value="Send Photo" />
  </form>
<?php
}
function displayThanks() {
>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Example Program

```
<form action="someform.php" method="post">
Name: <input type="text" name="Name" value="Jim" /> <br />
Password: <input type="password" name="Password" /> <br />
Age: <input type="text" name="Age" /> <br />
<input type="submit" />
</form>
```

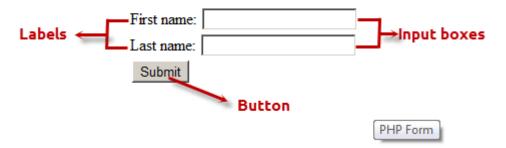

The code below creates a simple registration form

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Viewing the above code in a web browser displays the following form.

Registration Form

HERE,

- <form...>...</form> are the opening and closing form tags
- action="registration_form.php" method="POST"> specifies the destination URL and the submission type.
- First/Last name: are labels for the input boxes
- <input type="text"...> are input box tags
-

 is the new line tag
- <input type="hidden" name="form_submitted" value="1"/> is a hidden value that is used to check whether the form has been submitted or not
- <input type="submit" value="Submit"> is the button that when clicked submits the form to the server for processing

Submitting the form data to the server

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

The action attribute of the form specifies the submission URL that processes the data. The method attribute specifies the submission type.

GET and **POST**

Superglobal Array

To read the data from a form, we can use the following three superglobal variables.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Superglobal Array	Description
\$_GET	Contains all the field names and values sent by a form using the get method
\$_POST	Contains all the field names and values sent by a form using the post method
\$_REQUEST	Contains the values of both the \$_GET and \$_POST arrays combined, along with the values of the \$_COOKIE superglobal array

- When defining the method to send information to the PHP script, you either
 use GET or POST. Both send variables across to a script, but they do so in
 different ways.
- The GET method sends its variables in the web browsers URL, which makes it easy to see and possibly change the information that was sent. So this method should not be used when sending passwords or other sensitive information. It also should not be used for any actions that cause a change in the server, such as placing an order or updating a database. However, because the variables are displayed in the URL, it is possible to bookmark the page.
- The GET method has a limit on the amount of information than can be sent.

 As a result, if you send long variables using GET, you are likely to lose large amounts of them.
- The POST method sends its variables behind the scenes and has no limits on the amount of information to be sent. Because the variables are not displayed in the URL, it is not possible to bookmark the page.

The GET Method

The GET method sends the encoded user information appended to the page request. The page and the encoded information are separated by the ?character.

http://www.test.com/index.htm?name1=value1&name2=value2

It has the following syntax.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

```
<?php
$_GET['variable_name'];
?>
```

HERE

The GET method produces a long string that appears in your server logs, in the browser's Location: box.

The GET method is restricted to send upto 1024 characters only.

Never use GET method if you have password or other sensitive information to be sent to the server.

GET can't be used to send binary data, like images or word documents, to the server.

The data sent by GET method can be accessed using QUERY_STRING environment variable.

The PHP provides \$_GET associative array to access all the sent information using GET method.

Try out following example by putting the source code in test.php script.

```
<?php
 if( $_GET["name"] | | $_GET["age"] ) {
   echo "Welcome ". $_GET['name']. "<br />";
   echo "You are ". $_GET['age']. " years old.";
   exit();
 }
5>
<html>
  <body>
   <form action = "<?php $ PHP SELF ?>" method = "GET">
     Name: <input type = "text" name = "name" />
     Age: <input type = "text" name = "age" />
     <input type = "submit" />
   </form>
  </body>
</html>
```

It will produce the following result -

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

|--|

The POST Method

The POST method transfers information via HTTP headers. The information is encoded as described in case of GET method and put into a header called QUERY_STRING.

The POST method does not have any restriction on data size to be sent.

```
<?php
$_POST['variable_name'];
?>
```

The POST method can be used to send ASCII as well as binary data.

The data sent by POST method goes through HTTP header so security depends on HTTP protocol. By using Secure HTTP you can make sure that your information is secure.

The PHP provides \$_POST associative array to access all the sent information using POST method.

Try out following example by putting the source code in test.php script.

<form action = "<?php \$_PHP_SELF ?>" method = "POST">

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Name: <input name="name" type="text"/>	
Age: <input name="age" type="text"/>	
<pre>sinput type = "submit" /></pre>	
It will produce the following result -	

Name:	Age:	Submit

POST Vs GET METHOD

POST	GET
Values not visible in the URL	Values visible in the URL
Has not limitation of the length of the values since they are submitted via the body of HTTP	Has limitation on the length of the values usually 255 characters. This is because the values are displayed in the URL. Note the upper limit of the characters is dependent on the browser.
Has lower performance compared to Php_GET method due to time spent encapsulation the Php_POST values in the HTTP body	Has high performance compared to POST method dues to the simple nature of appending the values in the URL.
Supports many different data types such as string, numeric, binary etc.	Supports only string data types because the values are displayed in the URL
Results cannot be book marked	Results can be book marked due to the visibility of the values in the URL

GET Method

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

FORM ELEMENT LIST

The following table lists HTML elements in forms.

Element	Description
input type="checkbox"	A checkbox that lets users select multiple options.
input type="file"	A text box plus a button that opens a file selection dialog.
input type="hidden"	A hidden form element.
input type="password"	A password text box.
input type="radio"	A radio button.
input type="reset"	A button to clear the form.
input type="submit"	A button to submit the form.
input type="text"	A text box.
option	An option in a SELECT element.
select	A listbox; can also be a drop-down list box.
textarea	Multiline text box.

DEALING WITH MULTI VALUE FIELDS

- Treat the field as a nested array in the super global arrays
- Form fields can send multiple values, rather than a single value.

Form Select as Pull-down menu

A pull-down menu allows users to choose a single item from a predefined list of options. The size attribute's value of 1 tells the browser that you want the list to be in a pull-down menu format.

Within the select element, you create an option element for each of your options.

To place the option label between the <option> ... </option> tags.

Each option element can have an optional value attribute, which is the value sent to the server if that option is selected.

If you don't include a value attribute, the text between the <option> ... </option> tags is sent instead:

<label for="pullDownMenu">A pull-down menu</label>

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Form Select as List Box

A list box works like a pull-down menu, except that it displays several options at once.

To turn a pull-down menu into a list box, change the size attribute from 1 to the number of options to display at once:

Form Select as multi-select list box

A multi-select list box allows the user to select multiple items at once by holding down Ctrl or Command key.

To turn a normal list box into a multi-select box, add the attribute multiple with a value of "multiple" to the select element.

If the user selects more than one option, all the selected values are sent to the server:

You can preselect an option in any type of select element by adding the attribute selected="selected" to the relevant <option> tag - for example: <option value="option1" selected="selected">.

Example

<body>

<div>

KARPAGAM ACADEMY OF HIGHER EDUCATION

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

Name the following script as index.htm. It has a multi-select list box.

 $\frac{\text{html}}{\text{m}}$ jav a 2 s. c o m*/

```
<form action="index.php" method="post">
<select name="products[]" multiple="multiple">
 <option>A</option>
 <option>B</option>
 <option>C</option>
 <option>D</option>
</select>
<input type="submit" value="hit it!" />
</form>
</div>
</body>
</html>
The following script is for index.php.
<?php/*from java 2 s. com*/</pre>
 if (is_array ( $_POST ['products'] )) {
  print "Your product choices are:";
  print "";
  foreach ( $_POST ['products'] as $value ) {
   print "$value\n";
  print "";
5>
A checkbox field is a simple toggle button. It can be either on or off.
The value attribute should contain the value that will be sent to the server when the checkbox is
```

selected. If the checkbox isn't selected, nothing is sent.

<label for="checkboxField">A checkbox field</label>

```
<input type="checkbox" name="checkboxField" id="checkboxField" value="yes" />
Preselect a checkbox by adding the attribute checked "checked" to the input tag:
sinput type="checkbox" checked="checked" ... />.
By creating multiple checkbox fields with the same name attribute, you can allow the user to select
multiple values for the same field.
Example
The following script is for index.htm. It has several checkboxes.
<html>
<body>
<form action ="index.php">
<ii><input type ="checkbox" name ="chkFries" value ="11.00">Fries
    \li>\sinput type ="checkbox" name ="chkSoda" value ="12.85">Soda\li>\sinput type = "checkbox" name = "chkSoda" value = "12.85">Soda\li>\sinput type = "checkbox" name = "chkSoda" value = "12.85">Soda\li>\sinput type = "checkbox" name = "chkSoda" value = "12.85">Soda\li>\sinput type = "checkbox" name = "chkSoda" value = "12.85">Soda\li>\sinput type = "checkbox" name = "chkSoda" value = "12.85">Soda\li>\sinput type = "checkbox" name = "chkSoda" value = "12.85">Soda\li>\sinput type = "checkbox" name = "chkSoda" value = "12.85">Soda\li>\sinput type = "checkbox" name = "chkSoda" value = "12.85">Soda\li>\sinput type = "checkbox" name = "chkSoda" value = "12.85">Soda\li>\sinput type = "12.85">Soda\li>\
    <ii>\tip\tiput type = "checkbox" name = "chkShake" value = "1.30" \times Shake \left\[ \] i>
    <input type ="checkbox" name ="chkKetchup" value =".05">Ketchup
<input type ="submit">
</form>
</body>
</html>
The following code is for index.php and it accepts the value from the checkboxes.
<?PHP/*java2 s .c om*/
print "chkFries:" . $chkFries . "<br/>";
print "chkSoda:" $chkSoda . "<br/>";
print "chkShake:" . $chkShake . "<br/>";
print "chkKetchup" . $chkKetchup . "<br/>";
\text{$total} = 0;
```

```
if (!empty($chkFries)){
 print ("You chose Fries <br>");
 $total = $total + $chkFries;
}
if (!empty($chkSoda)){
 print ("You chose Soda <br>");
 $total = $total + $chkSoda;
}
if (!empty($chkShake)){
 print ("You chose Shake <br>");
 $total = $total + $chkShake;
if (!empty($chkKetchup)){
 print ("You chose Ketchup <br>");
 $total = $total + $chkKetchup;
print "The total cost is \$$total";
5>
For Example Program
<html>
    <head>
    <style>
     .error {color: #FF0000;}
    </style>
  </head>
  <body>
```

```

Classes: Gender: Female	Male *	

PHP REDIRECT AFTER A FORM SUBMISSION

- Redirection is done by outputting a Location using PHP using the header() function.
- ➤ Here's how to redirect to a page called thanks.html:
- ➤ header("Location: thanks.html");
- ➤ Don't output any content to the browser via echo() or print(), or by including HTML markup outside the <?php ... ?> tags before calling header().

When a browser receives information from the web server it receives an HTTP header (which the header() function outputs the redirect to), and then outputs the body of the HTTP response after the HTTP header.

```
<?php
// Process form
// If processing was successful, redirect
if($success)
{
// Replace your redirection URL here
header("Location: http://www.coolcakes.net/");
}</pre>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

?>

Example

Here's a quick example of a form handler script that redirects to a thank - you page:

```
<pphp</pre>
```

```
if ( isset( $_POST["submitButton"] ) ) {
// (deal with the submitted fields here)
 header("Location: thanks.html");
 exit;
} else {
 displayForm();
function displayForm() {
2>
<html>
 <body>
  <form action="index.php" method="post">
     <label for="firstName">First name</label>
     <input type="text" name="firstName" id="firstName" value="" />
     <label for="lastName">Last name</label>
     <input type="text" name="lastName" id="lastName" value="" />
     <input type="submit" name="submitButton" id="submitButton" value= "Send Details" />
  </form>
 </body>
</html>
<php</pre>
?>
```

PHP Conditional Statements

Conditional statements are used to perform different actions based on different conditions.

In PHP we have the following conditional statements:

1. if statement - executes some code if one condition is true

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

- 2. if...else statement executes some code if a condition is true and another code if that condition is false
- 3. if...elseif....else statement executes different codes for more than two conditions
- 4. switch statement selects one of many blocks of code to be executed

PHP - The if Statement

The if statement executes some code if one condition is true.

```
Syntax
if (condition) {
   code to be executed if condition is true;
}
```

The example below will output "Have a good day!" if the current time (HOUR) is less than 20:

```
Example
```

```
<?php
$t = date("H");

if ($t < "20") {
   echo "Have a good day!";
}
</pre>
```

PHP - The if...else Statement

The if....else statement executes some code if a condition is true and another code if that condition is false.

```
Syntax
```

```
if (condition) {
   code to be executed if condition is true;
} else {
   code to be executed if condition is false;
}
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

The example below will output "Have a good day!" if the current time is less than 20, and "Have a good night!" otherwise:

```
Example
<Pphp
$t = date("H");

if ($t < "20") {
    echo "Have a good day!";
} else {
    echo "Have a good night!";
}
</pre>
```

PHP - The if...elseif....else Statement

The if....elseif...else statement executes different codes for more than two conditions.

```
if (condition) {

code to be executed if this condition
```

} elseif (condition) {

code to be executed if this condition is true;

code to be executed if this condition is true;

code to be executed if all conditions are false;

The example below will output "Have a good morning!" if the current time is less than 10, and "Have a good day!" if the current time is less than 20. Otherwise it will output "Have a good night!":

```
Example
```

```
<php</pre>
```

Syntax

} else {

t = date("H");

if (\$t < "10") {

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

```
echo "Have a good morning!";
} elseif ($t < "20") {
   echo "Have a good day!";
} else {
   echo "Have a good night!";
}
```

PHP - The switch Statement

The switch statement is used to perform different actions based on different conditions.

The PHP switch Statement

Use the switch statement to select one of many blocks of code to be executed.

```
Syntax
switch (n) {
    case label1:
        code to be executed if n=label1;
        break;
    case label2:
        code to be executed if n=label2;
        break;
    case label3:
        code to be executed if n=label3;
        break;
...
    default:
    code to be executed if n is different from all labels;
```

This is how it works: First we have a single expression n (most often a variable), that is evaluated once. The value of the expression is then compared with the values for each case in the structure. If there is a match, the block of code associated with that case is executed. Use break to prevent the

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

code from running into the next case automatically. The default statement is used if no match is found.

```
Example
<pphp</pre>
$favcolor = "red";
switch ($favcolor) {
  case "red":
     echo "Your favorite color is red!";
     break;
  case "blue":
     echo "Your favorite color is blue!";
     break;
  case "green":
     echo "Your favorite color is green!";
     break;
  default:
     echo "Your favorite color is neither red, blue, nor green!";
}
?>
```

PHP Loops

Often when you write code, you want the same block of code to run over and over again in a row. Instead of adding several almost equal code-lines in a script, we can use loops to perform a task like this.

In PHP, we have the following looping statements:

- 1. while loops through a block of code as long as the specified condition is true
- 2. do...while loops through a block of code once, and then repeats the loop as long as the specified condition is true
- 3. for loops through a block of code a specified number of times
- 4. foreach loops through a block of code for each element in an array

The PHP while Loop

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

The while loop executes a block of code as long as the specified condition is true.

```
Syntax
while (condition is true) {
  code to be executed;
}
```

The example below first sets a variable x = 1. Then, the while loop will continue to run as long as x = 1. Sx will increase by 1 each time the loop runs (x = 1):

Example

```
<pphp
$x = 1;

while($x <= 5) {
    echo "The number is: $x <br>";
    $x++;
}
```

do...while Loop

The do...while loop will always execute the block of code once, it will then check the condition, and repeat the loop while the specified condition is true.

Syntax

```
do {
  code to be executed;
} while (condition is true);
```

The example below first sets a variable x to 1 (x = 1). Then, the do while loop will write some output, and then increment the variable x with 1. Then the condition is checked (is x less than, or equal to x?), and the loop will continue to run as long as x is less than, or equal to x?

```
Example
<pppp
$x = 1;
do {
    echo "The number is: $x <br>";
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

```
$x++;
} while ($x <= 5);
P>
```

do while loop the condition is tested AFTER executing the statements within the loop. This means that the do while loop would execute its statements at least once, even if the condition is false the first time.

The example below sets the \$x variable to 6, then it runs the loop, and then the condition is checked:

Example

```
<?php
$x = 6;
do {
    echo "The number is: $x <br>";
    $x++;
} while ($x <= 5);
?>
```

The PHP for Loop

The for loop is used when you know in advance how many times the script should run.

Syntax

```
for (init counter; test counter; increment counter) {
  code to be executed;
}
```

Parameters:

- init counter: Initialize the loop counter value
- ➤ test counter: Evaluated for each loop iteration. If it evaluates to TRUE, the loop continues. If it evaluates to FALSE, the loop ends.
- increment counter: Increases the loop counter value
- \triangleright The example below displays the numbers from 0 to 10:

```
Example
```

```
<?php
for ($x = 0; $x <= 10; $x++) {</pre>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

```
echo "The number is: $x <br>";
}
?>
```

PHP foreach Loop

The foreach loop works only on arrays, and is used to loop through each key/value pair in an array.

Syntax

```
foreach ($array as $value) {
  code to be executed;
}
```

For every loop iteration, the value of the current array element is assigned to \$value and the array pointer is moved by one, until it reaches the last array element.

The following example demonstrates a loop that will output the values of the given array (\$colors):

Example

```
<?php
$colors = array("red", "green", "blue", "yellow");
foreach ($colors as $value) {
   echo "$value <br>";
}
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: II (HTML form with PHP) BATCH-2017-2018

POSSIBLE QUESTIONS

Part B (2 Marks)

- 1. Difference between GET and POST Methods.
- 2. What are form elements PHP?
- 3. List out the multivalue fields in PHP.
- 4. Compare While and for while loop.
- 5. What it Goto and Break Statement.

Part C (6 Marks)

- 1. How to handle HTML forms in PHP with example.
- 2. Describe on multi value fields in PHP
- 3. How to redirect a form after submission with example program.
- 4. Explain in detail about conditional statements in PHP with example.
- 5. Discuss on different types of looping statements in PHP.

Department of Information Technology III B.Sc(IT) (BATCH 2017-2020) V

VI SEMESTER

PHP PROGRAMMING (17ITU601A) PART-A OBJECTIVE TYPE/ MULTIPLE CHOICE QUESTIONS UNIT II

CLASS: III B.Sc IT COURSE CODE: 17ITU601A COURSE NAME: PHP Programming UNIT: III (PHP Functions) BATCH-2017-2020

UNIT-III

PHP Functions:

Function, Need of Function, declaration and calling of a function-PHP Function with arguments, Default Arguments in Function-Function argument with call by value, call by reference-Scope of Function Global and Local

Function -Introduction

Functions are basically named scripts that can be called upon from any other script to perform a specific task. Values (known as arguments) can be passed into a function so that they can be used in the function script, and functions can, in turn, return results to the location from which they were called.

Need of PHP function

- ➤ Better code organization functions allow us to group blocks of related code that perform a specific task together.
- Reusability once defined, a function can be called by a number of scripts in our PHP files. This saves us time of reinventing the wheel when we want to perform some routine tasks such as connecting to the database
- Easy maintenance- updates to the system only need to be made in one place.

There are two basic types of functions. Built-in functions and user defined ones. The built-in functions are part of the PHP language.

User Defined Functions

Besides the built-in PHP functions, we can create our own functions.

- 1. A function is a block of statements that can be used repeatedly in a program.
- 2. A function will not execute immediately when a page loads.
- 3. A function will be executed by a call to the function.

Prepared by Dr.K.Devasenapathy, Associate Professor Department of CS, CA & IT, KAHE 1/32

CLASS: III B.Sc IT COURSE CODE: 17ITU601A COURSE NAME: PHP Programming UNIT: III (PHP Functions) BATCH-2017-2020

Declaration and Calling of a Function-in PHP

A user-defined function declaration starts with the word function:

Syntax

```
function functionName() {
  code to be executed;
}
```

The declaration of a user-defined function start with the word function, followed by the name of the function you want to create followed by parentheses i.e. () and finally place your function's code between curly brackets {}.

Note: A function name can start with a letter or underscore (not a number).

Example

```
<Pphp
function writeMsg() {
    echo "Hello world!";
}
writeMsg(); // call the function
P>
```

Calling PHP Functions

PHP functions are called by using the name declared when the function was defined, together with any values that need to be passed through as parameters. The following example both defines and then calls our addNumbers() function:

```
<Pphp
function addNumbers ($arg1, $arg2)
{
   return $arg1 + $arg2;</pre>
```

Prepared by Dr.K.Devasenapathy, Associate Professor Department of CS, CA & IT, KAHE 2/32

}

KARPAGAM ACADEMY OF HIGHER EDUCATION

CLASS: III B.Sc IT COURSE CODE: 17ITU601A COURSE NAME: PHP Programming UNIT: III (PHP Functions) BATCH-2017-2020

```
$var1 = 10;
$var2 = 20;
print addNumbers( $var1, $var2);
?>
```

When loaded into a browser the print statement will display the result returned by the addNumbers() function, in this case the number 30.

PHP Function Arguments

Information can be passed to functions through arguments. An argument is just like a variable.

Arguments are specified after the function name, inside the parentheses. You can add as many arguments as you want, just separate them with a comma.

The following example has a function with one argument (\$fname). When the familyName() function is called, we also pass along a name (e.g. Jani), and the name is used inside the function, which outputs several different first names, but an equal last name:

Example

```
<Pphp
function familyName($fname) {
    echo "$fname Refsnes.<br>";
}

familyName("Jani");
familyName("Hege");
familyName("Stale");
```

Prepared by Dr.K.Devasenapathy, Associate Professor Department of CS, CA & IT, KAHE 3/32

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: III (PHP Functions) BATCH-2017-2020

```
familyName("Kai Jim");
familyName("Borge");

?>

The following example has a function with two arguments ($fname and $year):
<?php
function familyName($fname, $year) {
   echo "$fname Refsnes. Born in $year <br/>};
}
familyName("Hege", "1975");
familyName("Stale", "1978");
familyName("Kai Jim", "1983");
?>
```

PHP Default Argument Value

The following example shows how to use a default parameter. If we call the function setHeight() without arguments it takes the default value as argument:

```
Example
<Pphp
function setHeight($minheight = 50) {
    echo "The height is : $minheight <br/>;
}

setHeight(350);
setHeight(); // will use the default value of 50
setHeight(135);
setHeight(80);
```

Prepared by Dr.K.Devasenapathy, Associate Professor Department of CS, CA & IT, KAHE 4/32

CLASS: III B.Sc IT COURSE CODE: 17ITU601A COURSE NAME: PHP Programming UNIT: III (PHP Functions) BATCH-2017-2020

Function argument with call by value

Call by value means passing the value directly to a function. The called function uses the value in a local variable; any changes to it **do not** affect the source variable.

Example

This is a "global", or automatic global, variable. This simply means that it is available in all scopes throughout a script. There is no need to do global \$x; to access it within functions or methods.

```
<?php
//Call by value program
function abc($x)
{
    $x=$x+10;
    return($x);
}
$a=20;
echo abc($a)."<br>";
echo ($a);
p>
```

Note: Call by value: in the call by value method, the called function creates a new set of variables and copies the values of arguments into them.

Function argument with call by reference

Call by reference means passing the address of a variable where the actual value is stored. The called function uses the value stored in the passed address; any changes to it **do** affect the source variable.

```
<?php
//call by reference program in php
function abc($x)</pre>
```

Prepared by Dr.K.Devasenapathy, Associate Professor Department of CS, CA & IT, KAHE 5/32

CLASS: III B.Sc IT COURSE CODE: 17ITU601A COURSE NAME: PHP Programming UNIT: III (PHP Functions) BATCH-2017-2020

```
{
    $x=$x-10;
    return($x);
}
$a=50;
echo abc($a)."<br>";
echo ($a);
}
```

Note: Call by reference: in the call by reference method, instead of passing a value to the function being called a reference/pointer to the original variable is passed.

SCOPE OF FUNCTION GLOBAL AND LOCAL

- 1. Variables declared outside of functions and classes are global. Global variables are available else where in the script.
- 2. Function variables are self-contained and do not affect variables in the main script.
- 3. Variables from the main script are not implicitly made available inside functions.

Example

```
Take a look at this example:
<PPHP

function foo() {
    $bar = "java2s.com";
}

$bar = "PHP";

foo();

print $bar;

p>
```

The code above generates the following result.

Prepared by Dr.K.Devasenapathy, Associate Professor Department of CS, CA & IT, KAHE 6/32

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: III (PHP Functions) BATCH-2017-2020

PHP

- Execution of the script starts at the \$bar = "PHP" line, and then calls the foo() function.
- > foo() sets \$bar to java2s.com, then returns control to the main script where \$bar is printed out.
- Function foo() is called, and, having no knowledge that a \$bar variable exists in the global scope, creates a \$bar variable in its local scope.
- > Once the function ends, all local scopes are gone, leaving the original \$bar variable intact.

PHP Global Variables

A global variable can be accessed anywhere in your script, whether inside or outside a function. In PHP, all variables created outside a function are, in a sense, global in that they can be accessed by any other code in the script that's not inside a function.

To use such a variable inside a function, write the word global followed by the variable name inside the function 's code block.

```
<PHP
    $myGlobal = "Hello there!";

function hello() {
    global $myGlobal;
    echo "$myGlobal\n";
    }
    hello(); // Displays "Hello there!"
P>
```

The code above generates the following result.

Hello there!

hello() function accesses the \$myGlobal variable by declaring it to be global using the global statement. The function can then use the variable to display the greeting.

Prepared by Dr.K.Devasenapathy, Associate Professor Department of CS, CA & IT, KAHE 7/32

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 17ITU601A UNIT: III (PHP Functions) BATCH-2017-2020

Example 1

Created a variable outside a function to use it as a global variable. Take a look at the following script:

```
<?PHP
```

```
function setup() {
    global $myGlobal;
    $myGlobal = "Hello there!";
}
function hello() {
    global $myGlobal;
    echo "$myGlobal\n";
}
setup();
hello(); // Displays "Hello there!"
```

The code above generates the following result.

Hello there!

In this script, the setup() function is called first. It declares the \$myGlobal variable as global, and gives it a value.

Then the hello() function is called. It too declares \$myGlobal to be global, which means it can now access its value previously set by setup() and display it.

Example 2

The \$GLOBALS array can access global variables within functions. All variables declared in the global scope are in the \$GLOBALS array, which you can access anywhere in the script. Here is a demonstration:

<?PHP

function foo() {

Prepared by Dr.K.Devasenapathy, Associate Professor Department of CS, CA & IT, KAHE 8/32

CLASS: III B.Sc IT COURSE CODE: 17ITU601A COURSE NAME: PHP Programming UNIT: III (PHP Functions) BATCH-2017-2020

```
$GLOBALS['bar'] = "java2s.com";
bar = "PHP";
foo();
print $bar;
2>
The code above generates the following result.
java2s.com
We can read variables in the same way:
$localbar = $GLOBALS['bar'];
PHP GLOBAL keyword allow a variable to be accessed locally.
function myfunc() {
  GLOBAL $foo, $bar, $baz;
  ++$baz;
The code above reads the global variables $foo, $bar, and $baz. The ++$baz line will increment
$baz by 1, and this will be reflected in the global scope.
Note
We can also declare more than one global variable at once on the same line, just separate the
variables using commas:
function myFunction() {
```

Be careful with global variables. If you modify the value of a global variable in many different places within your application, it can make it hard to debug your code.

global \$oneGlobal, \$anotherGlobal;

Prepared by Dr.K.Devasenapathy, Associate Professor Department of CS, CA & IT, KAHE 9/32

CLASS: III B.Sc IT COURSE CODE: 17ITU601A COURSE NAME: PHP Programming UNIT: III (PHP Functions) BATCH-2017-2020

POSSIBLE QUESTIONS

Part B (2 Marks)

- 1. Define Function.
- 2. How to declare the function?
- 3. Compare between Call by value and Call by reference.
- 4. What is the use of function?
- 5. Write short notes on scope of function.

Part C (6 Marks)

- 1. How to declaration and calling of a function in PHP? Explain it.
- 2. Explain in detail about PHP Function with arguments with example program.
- 3. Discuss about Default Arguments in Function with example.
- 4. Describe on Function argument with call by value, call by reference
- 5. Elucidate on Scope of Function in Global and Local.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

UNIT IV

String Manipulation and Regular Expression: Creating and accessing String , Searching & Replacing String-Formatting, joining and splitting String , String Related Library functions -Use and advantage of regular expression over inbuilt function-Use of preg_match(), preg_replace(), preg_split() functions in regular expression.

STRING MANIPULATION AND REGULAR EXPRESSION

A string is a sequence of letters, numbers, special characters and arithmetic values or combination of all. The simplest way to create a string is to enclose the string literal (i.e. string characters) in single quotation marks ('), like this:

\$my_string = 'Hello World';

We can also use double quotation marks ("). However, single and double quotation marks work in different ways. Strings enclosed in single-quotes are treated almost literally, whereas the strings delimited by the double quotes replaces variables with the string representations of their values as well as specially interpreting certain escape sequences.

The escape-sequence replacements are:

- ➤ \n is replaced by the newline character
- > \r is replaced by the carriage-return character
- > \t is replaced by the tab character
- ➤ \\$ is replaced by the dollar sign itself (\$)
- > \" is replaced by a single double-quote (")
- ➤ \\ is replaced by a single backslash (\)

Here's an example to clarify the differences between single and double quoted strings:

Example

```
<pphp
$my_str = 'World';
echo "Hello, $my_str!<br>";  // Displays: Hello World!
echo 'Hello, $my_str!<br>';  // Displays: Hello, $my_str!
echo 'Hello\tWorld!'; // Displays: Hello\tWorld!
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

```
echo "Hello\tWorld!"; // Displays: Hello World!
echo 'I\'ll be back'; // Displays: I'll be back
?>
```

There Are Many Numbers of Functions That Are Directly Concerned With Manipulating Strings

- > Search for text within a string
- > Calculate the string length
- > Break a string down into component parts
- ➤ Formatting of strings

Strings Functions

String functions like strlen, strsrt, strpos etc.

Php Strlen() Function

The length of the string using strlen() function.

Syntax of Strlen Function

Strlen(\$expression);

Strlen Example

```
<Pphp
$element = strlen("PHP");
echo $element." < br>";
echo strlen("welcome");
```

Searching Strings With Strstr() Function

Find out whether some text occurs within a string or not, using strstr() function ,if string match print all the string from where string matched. If word is not found strstr function return false.

Syntax Of Strstr() Function

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

```
Strstr( $expression ,search text );
Strsrt Example
<?php
$string1= "Hello world!";
echo strstr($string1, "H")."<br>";
echo (strstr($string1, "xyz")? "Yes": "No")."<br>";
$string2= "Welcome to php string";
echo strstr( $string1, "java" ) ."<br/>'; //nothing print
echo (strstr($string2, "php")? "Yes": "No")."<br/>';
5>
Accessing Characters within A String
To access the each characters of a string. To access a character at a particular position.
Syntax
$char = $str [ position ];
String Example
<?php
$myStr = "Welcome to the php string";
echo $myStr[0] ."<br/>"; // print "W"
echo $myStr[6] ."<br/>"; // print "e"
$myStr[25] = '?';//Welcome to the php string?
```

Replacing String

5>

echo \$myStr."
";

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

Definition and Usage

- ➤ The str_replace() function replaces some characters with some other characters in a string.
- > This function works by the following rules:
- ➤ If the string to be searched is an array, it returns an array
- ➤ If the string to be searched is an array, find and replace is performed with every array element
- ➤ If both find and replace are arrays, and replace has fewer elements than find, an empty string will be used as replace
- ➤ If find is an array and replace is a string, the replace string will be used for every find value

Syntax

str_replace(find,replace,string,count)

| Parameter Description | | |
|--|---|--|
| find Required. Specifies the value to find | | |
| replace | Required. Specifies the value to replace the value in <i>find</i> | |
| string | Required. Specifies the string to be searched | |
| count | Optional. A variable that counts the number of replacements | |

Example

Using str_replace() with an array and a count variable:

```
<?php
$arr = array("blue","red","green","yellow");
print_r(str_replace("red","pink",$arr,$i));
echo "Replacements: $i";</pre>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

?>

Formatting Strings

Concatenation

Concatenation is a programming word for adding strings together. In PHP, the concatenation operator is a dot (.). Generally, concatenation is used to combine literal text with variables or values returned from functions.

Example

```
<!DOCTYPE HTML>
<html>
<head>
<meta charset="UTF-8">
<title>Concatenation</title>
</head>
<body>
<h1>Concatenation</h1>
<?php
      $firstName = 'Paul':
      $greeting = 'Hello';
      echo $greeting . ' ' . $firstName . '!';
?>
<h2>Using Double Quotes to Avoid the Concatenation Operator </h2>
<php</pre>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

String Manipulation Functions

Trimming Strings				
Function	Description			
trim()	Removes whitespace at beginning and end of a string.			
ltrim()	Removes whitespace at the beginning of a string.			
rtrim()	Removes whitespace at the end of a string.			

Presentation					
Function	Description				
htmlentities()	Escapes all HTML entities.				
nl2br()	Inserts a tag before each newline character in a string.				
strtoupper()	Converts a string to uppercase.				
strtolower()	Converts a string to lowercase.				
ucfirst()	Converts the first character of a string to uppercase.				
ucwords()	Converts the first character of each word in a string to uppercase.				

Converting	Strings and Arrays
Function D	Description
explode() S	Splits a string into an array on a specified character or group of characters.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

Convertin	Converting Strings and Arrays				
	Function Description				
implode()	Converts an array into a string, placing a specified character or group of characters between each array element.				
join()	Same as implode().				

Substrings	
Function	Description
substr(str,pos)	Returns the substring from the character in position pos to
substr(str,pos)	the end of the string.
substr(str,-len)	Returns the substring from len characters from the end of
Substi (StrTerr)	the string to the end of the string.
substr(str,pos,len)	Returns a len length substring beginning with the character in
54554 (54)p 55,7217	position pos.
	Returns a substring beginning with the character in
substr(str,pos,-len)	position pos and chopping off the last len characters of the
	string.
	If the third argument (before_needle) is false (default), then it returns the part of the haystack from the needle on.
	it returns the part of the naystack from the needle on.
	If the third argument (before_needle) is true, then it returns
strstr(haystack,needle,before_needle)	the part of the haystack before the needle.
	The needle can be a string or an integer (or a number that
	can be converted to an integer).
	_
stristr(haystack,needle,before_needle)	
	Finds the position of the first occurrence of a specified
	needle in a haystack (string).
strpos(haystack,needle)	The needle can be a string or an integer (or a number that
	can be converted to an integer).
	Finds the position of the last occurrence of a specified
	needle in a haystack (string).
strrpos(haystack,needle)	neede in a naystack (sunig).
surposmaystack, needie)	The needle can be a string or an integer (or a number that
	can be converted to an integer).
str_replace()	Replaces all occurrences of one string with another string.

Comparing Strings

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

Function	Description
cfrcmn()	Compares two strings. Returns < 0 if str1 is less than str2, > 0 if str1 is greater than
_	str2, and 0 if they are equal. Like strcmp() but case <i>in</i> sensitive.
	Returns the length of a string.

JOINING STRING

Joining String means Compensation Operator is used to combine character strings.

Operator	Description
·	The PHP concatenation operator (.) is used to combine two string values to create one string.
.=	Concatenation assignment which appends the argument on the right side to the argument on the left side.

Example

```
<?php
    $name="John";
    $lastName="Travolta";
    echo $name." ".$lastName; // Outputs John Travolta
    $a="Hello";
    $a .= " John!";
    echo $a; // Outputs Hello John!
?>
```

SPLITTING STRING

Definition and Usage

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

- ➤ The split() function will divide a string into various elements, the boundaries of each element based on the occurrence of pattern in string.
- ➤ The optional input parameter limit is used to signify the number of elements into which the string should be divided, starting from the left end of the string and working rightward.
- ➤ In cases where the pattern is an alphabetical character, split() is case sensitive.

Syntax

array split (string pattern, string string [, int limit])

Return Value

Returns an array of strings after splitting up a string.

Example

Following is the piece of code, copy and paste this code into a file and verify the result.

```
<5bb/>b
```

```
$ip = "123.456.789.000"; // some IP address
$iparr = split ("\.", $ip);
print "$iparr[0] <br/>";
print "$iparr[1] <br/>";
print "$iparr[2] <br/>";
print "$iparr[3] <br/>";

This will produce the following result —
```

123

456

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

789

000

str_split() Function

The str_split() is an inbuilt function in PHP and is used to convert the given string into an array. This function basically splits the given string into smaller strings of length specified by the user and stores them in an array and returns the array.

Syntax:

array str_split(\$org_string, \$splitting_length)

Parameters:

The function accepts two parameters and are described below:

- 1. \$org_string (mandatory): This refers to the original string that the user needs to split into an array.
- 2. \$splitting_length (optional): This refers to the length of each array element, we wish to split our string into. By default the function accepts the value as 1.

Return Values: The function returns an array. If the length parameter exceeds the length of the original string, then the whole string is returned as a single element. If the length parameter is less than 1, then False is returned. By default length is equal to 1.

Examples:

```
<?php
// PHP program to display the working of str_split()
$string = "Geeks";
// Since second argument is not passed,
// string is split into substrings of size 1.</pre>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

```
print_r(str_split($string));
$string = "GeeksforGeeks";
// Splits string into substrings of size 4
// and returns array of substrings.
print_r(str_split($string, 4))
5>
Output:
Array
  [0] => G
  [1] => e
  [2] = e
  [3] = k
  [4] => s
)
Array
  [0] => Geek
  [1] \Rightarrow sfor
  [2] => Geek
  [3] = > s
```

STRING RELATED LIBRARY FUNCTIONS

1. PHP strtolower() function

The strtolower() function returns string in lowercase letter.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

Syntax
string strtolower (string \$string)
Example
<pphp
\$str="My name is KHAN";
\$str=strtolower(\$str);
echo \$str;
p>
Output:
my name is khan

2. PHP strtoupper() function

The strtoupper() function returns string in uppercase letter.

Syntax

string strtoupper (string \$string)

Example

<Pphp</pre>

\$str="My name is KHAN";

\$str=strtoupper(\$str);

echo \$str;

5>

Output:

MY NAME IS KHAN

3. PHP ucfirst() function

The ucfirst() function returns string converting first character into uppercase. It doesn't change the case of other characters.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

Syntax string ucfirst (string \$str) Example <pphp \$str="my name is KHAN"; \$str=ucfirst(\$str); echo \$str; >> Output: My name is KHAN

4.PHP lcfirst() function

The lcfirst() function returns string converting first character into lowercase. It doesn't change the case of other characters.

Syntax

string lcfirst (string \$str)

Example

>php

\$str="MY name IS KHAN";

\$str=lcfirst(\$str);

echo \$str;

?>

Output:

mY name IS KHAN

5.PHP ucwords() function

The ucwords() function returns string converting first character of each word into uppercase.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

```
Syntax
       string ucwords (string $str)
       Example
       <?php
       $str="my name is Sonoo jaiswal";
       $str=ucwords($str);
       echo $str;
       >
       Output:
       My Name Is Sonoo Jaiswal
6. PHP strrev() function
       The strrey() function returns reversed string.
       Syntax
       string strrey (string $string)
       Example
       >php
       $str="my name is Sonoo jaiswal";
       $str=strrev($str);
       echo $str;
       ?>
       Output:
       lawsiaj oonoS si eman ym
7. PHP strlen() function
       The strlen() function returns length of the string.
       Syntax
       int strlen (string $string)
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

Example

<Pphp
\$str="my name is Sonoo jaiswal";
\$str=strlen(\$str);
echo \$str;
P>
Output:
24

REGULAR EXPRESSIONS

- Regular expressions are powerful pattern matching algorithm that can be performed in a single expression.
- \triangleright Regular expressions use arithmetic operators such as $(+,-,^{\wedge})$ to create complex expressions.
- ➤ Regular expressions help you accomplish tasks such as validating email addresses, IP address etc.

Use of regular expressions

- Regular expressions simplify identifying patterns in string data by calling a single function.
 This saves us coding time.
- ➤ When validating user input such as email address, domain names, telephone numbers, IP addresses,
- ➤ Highlighting keywords in search results
- ➤ When creating a custom HTML template. Regular expressions can be used to identify the template tags and replace them with actual data.

Regular expressions in PHP

PHP has built in functions that allow us to work with regular functions. Let's now look at the commonly used regular expression functions in PHP.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

- 1. preg_match this function is used to perform a pattern match on a string. It returns true if a match is found and false if a match is not found.
- 2. preg_split this function is used to perform a pattern match on a string and then split the results into a numeric array
- 3. preg_replace this function is used to perform a pattern match on a string and then replace the match with the specified text.

Below is the syntax for a regular expression function such as preg_match,preg_split or preg_replace.

<pphp</pre>

function_name('/pattern/',subject);

5>

HERE,

- ➤ "function_name(...)" is either preg_match, preg_split or preg_replace.
- > "/.../" The forward slashes denote the beginning and end of our regular expression
- > "/pattern/" is the pattern that we need to matched
- > "subject" is the text string to be matched against

PHP Preg_match

The first example uses the preg_match function to perform a simple pattern match for the word guru in a given URL.

The code below shows the implementation for the above example.

<pphp</pre>

\$my url = "www.guru99.com";

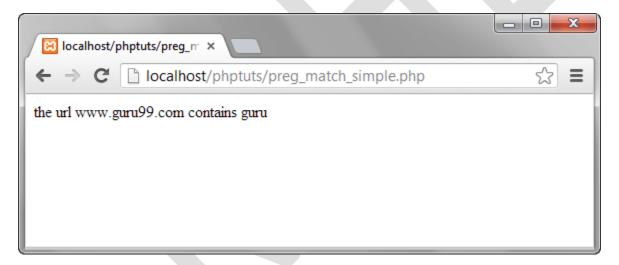

if (preg_match("/guru/", \$my_url))

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

```
echo "the url $my_url contains guru";
}
else
{
echo "the url $my_url does not contain guru";
}

P>
```

Output

PHP Preg_split

We will take a string phrase and explode it into an array; the pattern to be matched is a single spa

The text string to be used in this example is "I Love Regular Expressions".

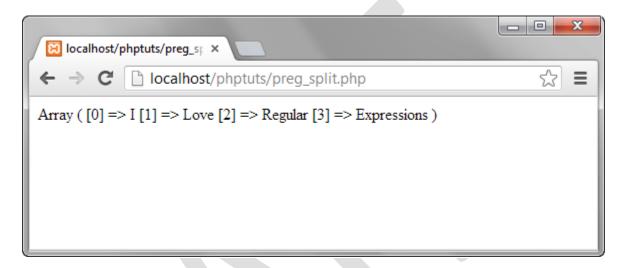

The code below illustrates the implementation of the above example.

<pphp</pre>

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

```
$my_text="I Love Regular Expressions";
$my_array = preg_split("//", $my_text);
print_r($my_array );
}
```

PHP Preg_replace

The preg_replace function that performs a pattern match and then replaces the pattern with something else.

The code below searches for the word guru in a string.

It replaces the word guru with the word guru surrounded by css code that highlights the background colour.

<?php</p>

\$text = "We at Guru99 strive to make quality education affordable to the masses. Guru99.com";

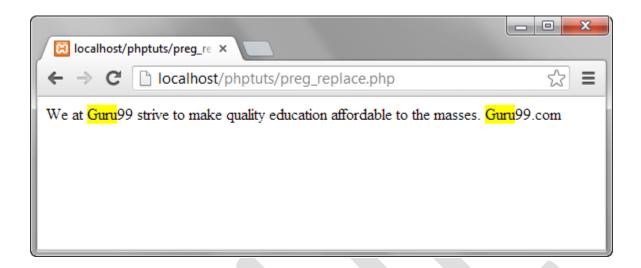

\$text = preg_replace("/Guru/", 'Guru', \$text);

echo \$text;

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

5>

Meta characters

The above examples used very basic patterns; metacharacters simply allow us to perform more complex pattern matches such as test the validity of an email address. Let's now look at the commonly used meta characters.

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

| | Description | Example |
|-----|--|--|
| ٠ | Matches any single character except a new line | /./ matches anything that has a single character |
| ^ | Matches the beginning of or string / excludes characters | /^PH/ matches any string that starts with PH |
| \$ | Matches pattern at the end of the string | /com\$/ matches guru99.com,ya hoo.com Etc. |
| * | Matches any zero (0) or more characters | /com*/ matches computer, communication etc. |
| + | Requires preceding character(s) appear at least once | /yah+oo/ matches yahoo |
| \ | Used to escape meta characters | /yahoo+\.com/ treats the dot as a literal value |
| [] | Character class | /[abc]/ matches abc |
| a-z | Matches lower case letters | /a-z/ matches cool, happy etc. |
| A-Z | Matches upper case letters | /A-Z/ matches WHAT,
HOW, WHY etc. |
| 0-9 | Matches any number between 0 and 9 | /0-4/ matches 0,1,2,3,4 |

The above list only gives the most commonly used metacharacters in regular expressions.

Example that checks the validity of an email address.

```
<?php
$my_email = "name@company.com";
if (preg_match("/^[a-zA-Z0-9._-]+@[a-zA-Z0-9-]+\.[a-zA-Z.]{2,5}$/", $my_email)) {
  echo "$my_email is a valid email address";
}
else
{
  echo "$my_email is NOT a valid email address";
}</pre>
```

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

?>

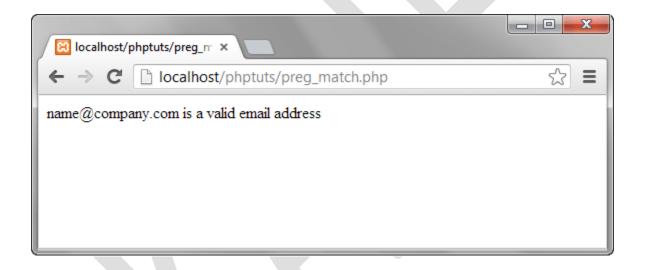

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

Explaining the pattern "[/^[a-zA-Z0-9._-]+@[a-zA-Z0-9-]+\.[a-zA-Z.]{2,5}\$/]"

HERE,

- > "/.../" starts and ends the regular expression
- ➤ "^[a-zA-Z0-9._-]" matches any lower or upper case letters, numbers between 0 and 9 and dots, underscores or dashes.
- ➤ "+@[a-zA-Z0-9-]" matches the @ symbol followed by lower or upper case letters, numbers between 0 and 9 or dashes.
- "+\.[a-zA-Z.] $\{2,5\}$ \$/" escapes the dot using the backslash then matches any lower or upper case letters with a character length between 2 and 5 at the end of the string.

KARPAGAM ACADEMY OF HIGHER EDUCATION (Deemed to be University) (Established under Section 5 of USE.

KARPAGAM ACADEMY OF HIGHER EDUCATION

CLASS: III B.Sc IT COURSE NAME: PHP Programming COURSE CODE: 16ITU601A UNIT: IV (STRING MANIPULATION) BATCH-2017-2019

POSSIBLE QUESTIONS

Part B (2 Marks)

- 1. How to create a String?
- 2. What is the use of regular expression?
- 3. Mention advantage of regular expression.
- 4. List out the types of functions in regular expression.
- 5. Define String.

Part C (6 Marks)

- 1. Explain in detail about Searching & Replacing String-Formatting.
- 2. Describe about joining and splitting String in PHP
- 3. List out the String Library functions and explain it with example.
- 4. Depict on use and advantage of regular expression over inbuilt function.
- 5. Discuss on preg_match(), preg_replace(), preg_split() functions in regular expression.

Department of Information Technology

III B.Sc(IT) (BATCH 2017-2020)

VI SEMESTER

PHP PROGRAMMING (17ITU601A)

PART-A OBJECTIVE TYPE/ MULTIPLE CHOICE QUESTIONS

UNIT IV

S.NO	QUESTIONS	OPT 1	OPT 2	OPT 3	OPT 4	ANSWER
1	A is a sequence of letters, numbers, special characters and arithmetic values or combination of all	array	string	structures	functions	string
2	PHP only supports acharacter set	256	128	64	32	256
3	PHP string can be as large as	less than 100MB	1KB	2GB	less than 2GB	2GB
4	the easiest way to specify string in PHP.	single quoted	double quoted	heredoc	newdoc	single quoted
5	We can store multiple line text, special characters and escape sequences in a PHP string.	single quoted	double quoted	heredoc	newdoc	double quoted
6	In strings, variable will be interpreted	single quoted	double quoted	heredoc	newdoc	double quoted
7	is used to create string in PHP with more lines but without using quotations	single quoted	double quoted	heredoc	newdoc	heredoc
8	heredoc starts with theoperator	<<	##	<<<	""	<<<

9	no parsing is done inside a	nowdoc	single quoted	double quoted	heredoc	nowdoc
10	function enables to display of the number of words in any specific string	str_word()	count()	str_word_ count()	word()	str_word_ count()
11	enables searching particular text within a string	pos()	stringpos()	strpos()	position()	strpos()
12	function is used for replacing specific text within a string	replace()	string_rep()	text_rep()	str_replace()	str_replace()
13	function is used for repeating a string a specific number of times	str_ repeat()	string_ rep()	text_rep()	repeat()	str_repeat()
14	You can compare two strings by using	strcmp()	comp()	string_ cmp()	str_cmp()	strcmp()
15	Through function you can display or extract a string from a particular position	substr()	extract()	sub()	sub_ext()	substr()
16	is dedicated to remove white spaces and predefined characters from a both the sides of a string.	remove()	sub()	white()	Trim()	Trim()
17	The function writes a formatted string to a variable	printf()	echo()	sprintf()	format()	sprintf()
18	A placeholder is inserted after the sign in a sprint()	&	%	*	\$	%
19	Thefunction returns a string from the elements of an array.	explode()	join()	split()	array()	join()
20	The join() function is an alias of the function	implode()	explote()	split()	array()	implode()
21	The function breaks a string into an array	split()	array()	break()	explode()	explode()

22	The parameter cannot be an empty string	separator	function	string	format	separator
23	The function returns string in lowercase letter	lower()	strtolower()	str_low()	string()	strtolower()
24	The function returns string in uppercase letter	upper()	ucase()	strtoupper()	string()	strtoupper()
25	The function returns string converting first character into uppercase	upper()	ucase()	strtoupper()	ucfirst()	ucfirst()
26	The function returns string converting first character into lowercase	lower()	strlower()	lcfirst()	string()	lcfirst()
27	The function returns string converting first character of each word into uppercase	ucwords()	lcfirst()	string()	upper()	ucwords()
28	Thefunction returns reversed string	reverse()	strrev()	str_rev()	string()	strrev()
29	The function returns length of the string	strlen()	length()	str_len()	lg()	strlen()
30	Regular expressions use operators to create complex expressions	binary	assignment	arithmetic	logical	arithmetic
31	can be used to identify the template tags and replace them with actual data.	string fucntions	Regular expressions	arrays	assocaitive arrays	Regular expressions
32	function is used to perform a pattern match on a string	preg_ match	preg_ split	preg_ replace	pre_exp	preg_match
33	function is used to perform a pattern match on a string and then split the results into a numeric array	preg_ match	preg_ split	preg_ replace	pre_exp	preg_ split

34	function is used to perform a pattern match on a string and then replace the match with the specified text	preg_ match	preg_ split	preg_ replace	pre_exp	preg_ replace
35	PHP does not support	Unicodes	EBIDIC	binary	ASCII	Unicodes
36	Escape sequences and variables will be interpreted using PHP strings.	double quote	single quoted	heredoc	newdoc	double quote
37	Strings that are delimited by are preprocessed	single quotes	heredoc	double quotes	newdoc	double quotes
38	is replaced by the carriage-return character	\c	\r	\v	\b	\r
39	is replaced by a single backslash (\)	\\	@	%	*	\\
40	In sprint() the arg1, arg2, ++ parameters will be inserted at	@	%	&	#	%
41	represents binary number	%bin	%binary	%b	%zero	%b
42	can be used when you want to extract or replace more than 1 character	repalce()	substr_ replace()	ext()	sub()	substr_ replace()
43	function is also useful in validation of input fields	validate()	str_word_ count()	check()	count()	str_word_ count()

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

UNIT-V

Array:

Anatomy of an Array ,Creating index based and Associative array, Accessing array-Looping with Index based array, with associative array using each() and foreach() -Some useful Library function

PHP Array

Arrays in PHP is a type of data structure that allows us to store multiple elements of similar data type under a single variable thereby saving us the effort of creating a different variable for every data. The arrays are helpful to create a list of elements of similar types, which can be accessed using their index or key.

An array is created using an array () function in PHP.

There are basically three types of arrays in PHP:

- 1. Indexed or Numeric Arrays: An array with a numeric index where values are stored linearly.
- 2. Associative Arrays: An array with a string index where instead of linear storage, each value can be assigned a specific key.
- 3. Multidimensional Arrays: An array which contains single or multiple array within it and can be accessed via multiple indices.

Numeric & Indexed Arrays

- These arrays can store numbers, strings and any object but their index will be represented by numbers. By default array index starts from zero.
- Numeric arrays use number as access keys.
- An access key is a reference to a memory slot in an array variable.
- ➤ The access key is used whenever we want to read or assign a new value an array element.

Below is the syntax for creating numeric array in php.

<?php

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

```
$variable_name[n] = value;

?>
Or
<?php

$variable_name = array(n => value, ...);
?>
HERE,
```

- > "\$variable_name..." is the name of the variable
- "[n]" is the access index number of the element
- "value" is the value assigned to the array element.

Example

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

```
$numbers[2] = "three";
      \sum_{i=1}^{n} [3] = four;
      numbers[4] = "five";
     foreach( $numbers as $value ) {
       echo "Value is $value <br />";
   5>
  </body>
</html>
This will produce the following result –
       Value is 1
       Value is 2
       Value is 3
       Value is 4
       Value is 5
       Value is one
       Value is two
       Value is three
       Value is four
       Value is five
```

Associative Arrays

- In an associative array, the keys assigned to values can be arbitrary and user defined strings.
- Associative array differ from numeric array in the sense that associative arrays use descriptive names for id keys.

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

Syntax for associative arrays:

array(key=>value,key=>value,etc.);

Parameter	Description
key	Specifies the key (numeric or string)
value	Specifies the value

For Example

To store the salaries of employees in an array, a numerically indexed array would not be the best choice. Instead, we could use the employees names as the keys in our associative array, and the value would be their respective salary.

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

echo "Salary of mohammad is ". \$salaries['mohammad'] . "
";
echo "Salary of qadir is ". \$salaries['qadir']. "
";
echo "Salary of zara is ". \$salaries['zara']. "
";
?>
</body>
</html>
This will produce the following result —
Salary of mohammad is 2000
Salary of qadir is 1000
Salary of zara is 500
Salary of mohammad is high
Salary of qadir is medium
Salary of zara is low

Multidimensional Arrays

Multi-dimensional arrays are such arrays which stores an another array at each index instead of single element. In other words, we can define multi-dimensional arrays as array of arrays. As the name suggests, every element in this array can be an array and they can also hold other sub-arrays within. Arrays or sub-arrays in multidimensional arrays can be accessed using multiple dimensions.

Example Program

<?php

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

```
// Defining a multidimensional array
$favorites = array(
  array(
     "name" => "Dave Punk",
     "mob" => "5689741523",
     "email" => "davepunk@gmail.com",
  ),
  array(
     "name" => "Monty Smith",
     "mob" => "2584369721",
     "email" => "montysmith@gmail.com",
  ),
  array(
     "name" => "John Flinch",
     "mob" => "9875147536",
     "email" => "johnflinch@gmail.com",
  )
);
// Accessing elements
echo "Dave Punk email-id is: " . $favorites[0]["email"], "\n";
```

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

echo "John Flinch mobile number is: " . \$favorites[1]["mob"];

?>

Output

Dave Punk email-id is: davepunk@gmail.com

John Flinch mobile number is: 2584369721

LOOPING WITH INDEX BASED ARRAY

There are two ways to create indexed arrays.

- First way to use array() function without any index, index are assigned automatically starting from 0.
- Second way to manually assign index and create the array.

PHP count() function is used to get the length of an array. We can use for loop to loop through all the values of an indexed array.

Example Program

```
<?php
$colors = array("Red","Green","Blue");
$colors1[0] = "Red";
$colors1[1] = "Green";
$length = count($colors);
echo "colors array length=" . $length; // prints "colors array length=3"
echo "<br/>
colors1 array length=" . count($colors1); // prints "colors1 array length=2"
```

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

```
//looping an indexed array

for($i=0; $i<$length; $i++){

   echo $colors[$i];

   echo "<br/>";
}
```

Associative Array Using Each ()

each - Return the current key and value pair from an array and advance the array cursor

Syntax

```
array each (array &$array)
```

Return the current key and value pair from an array and advance the array cursor.

After each() has executed, the array cursor will be left on the next element of the array, or past the last element if it hits the end of the array.

Example

```
$\text{Pphp}
$foo = array("bob", "fred", "jussi", "jouni", "egon", "marliese");
$\text{bar} = \text{each($foo);}
$\text{print_r($bar);}
$\text{P}$
```

Output

Array

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

```
[1] => bob
   [value] => bob
   [0] => 0
   [\text{key}] \Rightarrow 0
)
Example
<?php
$foo = array("Robert" => "Bob", "Seppo" => "Sepi");
bar = each(foo);
print_r($bar);
5>
Output
Array
  [1] => Bob
   [value] \Rightarrow Bob
   [0] => Robert
   [key] \Rightarrow Robert
```

Associative array using foreach()

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

Associative arrays uses named keys for values and we can create them in similar way like indexed arrays. foreach is used to loop through an associative array.

```
Syntax
foreach ($array as $value) {
  code to be executed;
}
Example
<pphp</p>
$colors = array("red", "green", "blue", "yellow");
foreach ($colors as $value) {
  echo "$value <br>";
}
5>
Output
red
green
blue
yellow
Example
<pphp</p>
```

\$colors = array("0"=>"Red","1"=>"Green","2"=>"Blue");

echo "0th element of array is " . \$colors["0"];

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

```
echo "<br/>
//looping

foreach ($colors as $key=>$value){
    echo "Key=".$key." value=".$value;
    echo "<br/>
';
}
```

Output of above PHP script is:

0th element of array is Red

Key=0 value=Red

Key=1 value=Green

Key=2 value=Blue

SOME USEFUL LIBRARY FUNCTION

<u>Function</u>	<u>Explanation</u>	<u>Example</u>
sizeof(\$arr)	This function returns the number of elements in an array. Use this function to find out how many elements an array contains; this information is most commonly used to initialize a loop counter when processing the	Code: \$data = array("red", "green", "blue"); echo "Array has " . sizeof(\$data) . " elements"; ?> Output: Array has 3 elements

CLASS: III B.Sc IT COURSE CODE: 16CTU601A

	array.	
array_values(\$arr)	This function accepts a PHP array and returns a new array containing only its values (not its keys). Its counterpart is the array_keys() function. Use this function to retrieve all the values from an associative array.	Code: \$data = array("hero" => "Holmes", "villain" => "Moriarty"); print_r(array_values(\$data)); ?> Output: Array ([0] => Holmes [1] => Moriarty)
array_keys(\$arr)	This function accepts a PHP array and returns a new array containing only its keys (not its values). Its counterpart is the array_values() function. Use this function to retrieve all the keys from an associative array.	Code: \$data = array("hero" => "Holmes", "villain" => "Moriarty"); print_r(array_keys(\$data)); ?> Output: Array ([0] => hero [1] => villain)
array_pop(\$arr)	This function removes an element from the end of an array.	Code: \$data = array("Donald", "Jim", "Tom"); array_pop(\$data); print_r(\$data); ?> Output: Array ([0] => Donald [1] => Jim)
array_push(\$arr,	This function adds an	Code:

CLASS: III B.Sc IT COURSE CODE: 16CTU601A

\$val)	element to the end of an array.	<pre>\$data = array("Donald", "Jim", "Tom"); array_push(\$data, "Harry"); print_r(\$data); ?> Output: Array ([0] => Donald [1] => Jim [2] => Tom [3] => Harry)</pre>
array_shift(\$arr)	This function removes an element from the beginning of an array.	Code: \$data = array("Donald", "Jim", "Tom"); array_shift(\$data); print_r(\$data); ?> Output: Array ([0] => Jim [1] => Tom)
array_unshift(\$arr, \$val)	This function adds an element to the beginning of an array.	Code: \$data = array("Donald", "Jim", "Tom"); array_unshift(\$data, "Sarah"); print_r(\$data); ?> Output: Array ([0] => Sarah [1] => Donald [2] => Jim [3] => Tom)

CLASS: III B.Sc IT COURSE CODE: 16CTU601A

each(\$arr)	This function is most often used to iteratively traverse an array. Each time each() is called, it returns the current key-value pair and moves the array cursor forward one element. This makes it most suitable for use in a loop.	Code: \$data = array("hero" => "Holmes", "villain" => "Moriarty"); while (list(\$key, \$value) = each(\$data)) { echo "\$key: \$value \n"; } ?> Output: hero: Holmes villain: Moriarty
sort(\$arr)	This function sorts the elements of an array in ascending order. String values will be arranged in ascending alphabetical order. Note: Other sorting functions include asort(), arsort(), ksort(), krsort() and rsort().	Code: \$data = array("g", "t", "a", "s"); sort(\$data); print_r(\$data); ?> Output: Array ([0] => a [1] => g [2] => s [3] => t)
array_flip(\$arr)	The function exchanges the keys and values of a PHP associative array. Use this function if you have a tabular (rows and columns) structure in an array, and you want to interchange the rows and columns.	Code: \$data = array("a" => "apple", "b" => "ball"); print_r(array_flip(\$data)); ?> Output: Array ([apple] => a [ball] => b)
array_reverse(\$arr)	The function reverses the order of elements in an array. Use this function to re-	Code: \$data = array(10, 20, 25, 60); print_r(array_reverse(\$data)); ?>

CLASS: III B.Sc IT COURSE CODE: 16CTU601A

	order a sorted list of values in reverse for easier processing—for example, when you're trying to begin with the minimum or maximum of a set of ordered values.	Output: Array ([0] => 60 [1] => 25 [2] => 20 [3] => 10
array_merge(\$arr)	This function merges two or more arrays to create a single composite array. Key collisions are resolved in favor of the latest entry. Use this function when you need to combine data from two or more arrays into a single structure—for example, records from two different SQL queries.	Code: \$data1 = array("cat", "goat"); \$data2 = array("dog", "cow"); print_r(array_merge(\$data1, \$data2)); ?> Output: Array ([0] => cat [1] => goat [2] => dog [3] => cow)
array_rand(\$arr)	This function selects one or more random elements from an array. Use this function when you need to randomly select from a collection of discrete values—for example, picking a random color from a list.	Code: \$data = array("white", "black", "red"); echo "Today's color is " . \$data[array_rand(\$data)]; ?> Output: Today's color is red
array_search(\$search, \$arr)	This function searches the values in an array for a match to the search term, and returns the	Code: \$data = array("blue" => "#0000cc", "black" => "#000000", "green" => "#00ff00"); echo "Found".

CLASS: III B.Sc IT COURSE CODE: 16CTU601A

	1: 1: 'C	
	corresponding key if found. If more than one match exists, the key of the first matching value is returned.	array_search("#0000cc", \$data); ?> Output: Found blue
	Use this function to scan a set of index-value pairs for matches, and return the matching index.	
array_slice(\$arr, \$offset, \$length)	This function is useful to extract a subset of the elements of an array, as another array. Extracting begins from array offset \$offset and continues until the array slice is \$length elements long. Use this function to break a larger array into smaller ones—for example, when segmenting an array by size ("chunking") or type of data.	Code: \$data = array("vanilla", "strawberry", "mango", "peaches"); print_r(array_slice(\$data, 1, 2)); ?> Output: Array ([0] => strawberry [1] => mango)
array_unique(\$data)	This function strips an array of duplicate values. Use this function when you need to remove non-unique elements from an array—for example, when creating an array to hold values for a table's primary key.	Code: \$data = array(1,1,4,6,7,4); print_r(array_unique(\$data)); ?> Output: Array ([0] => 1 [3] => 6 [4] => 7 [5] => 4)

CLASS: III B.Sc IT COURSE CODE: 16CTU601A

array_walk(\$arr, \$func)	This function "walks" through an array, applying a user-defined function to every	Code: function reduceBy10(&\$val, \$key) { \$val -= \$val * 0.1;
	element. It returns the changed array.	}
	Use this function if you	\$data = array(10,20,30,40); array_walk(\$data, 'reduceBy10');
	need to perform custom processing on	print_r(\$data); ?>
	every element of an array—for example,	Output:
	reducing a number	Array
	series by 10%.	([0] => 9
		[1] => 18
		[2] => 27 [3] => 36
)

CLASS: III B.Sc IT COURSE CODE: 16CTU601A COURSE NAME: PHP Programming UNIT: V (ARRAY) BATCH-2017-2020

POSSIBLE QUESTIONS

Part B (2 Marks)

- 1. Define Array.
- 2. What is difference between each() and foreach()?
- 3. What to access the array?
- 4. List out the library function of array.
- 5. How to create indexed based Array

Part C (6 Marks)

- 1. Describe about Associative array in PHP.
- 2. How to use looping with Index based array and explain it.
- 3. Explain in detail about associative array using each() and foreach().
- 4. Discuss on Library function in Array.
- 5. Write in detail about anatomy of an Array.

Department of Information Technology

III B.Sc(IT) (BATCH 2017-2020)

VI SEMESTER

PHP PROGRAMMING (17ITU601A)

PART-A OBJECTIVE TYPE/ MULTIPLE CHOICE QUESTIONS

UNIT V

S.N O	QUESTIONS	OPT 1	OPT 2	OPT 3	OPT 4	ANSWER
1	An is a special variable, which can hold more than one value at a time	literal	array	keywords	index	array
2	You can access the array values by referring to an	counter	keywords	index number	variable	index number
3	Thefunction is used to create an array	array()	arr()	new()	create()	array()
4	arrays are with a numeric index	associative	indexed	multiple	declarative	indexed
5	arrays are with named keys	associative	indexed	multiple	declarative	associative
6	arrays containing one or more arrays	associative	indexed	declarative	Multidimension	Multidimensional
7	In index array , the index always starts at	0	1	2	3	0
8	The function is used to return the length of an array	length()	term()	index()	count()	count()

9	To loop through and print all the values of an indexed array, you could use aloop	do	foreach	for	do while	for
10	To loop through and print all the values of an associative array, you could use a loop	do	foreach	do while	for	foreach
11	we can define arrays as array of arrays.	associative	indexed	declarative	Multidimension	Multidimension al
12	Array elements can be accessed using the syntax	index[key]	array[key]	element [key]	access[key]	array[key]
13	To handle a multiple-item return value from an array, you can use thefunction	return	list	display	array	list
14	arrays are similar to Map in java	associative	indexed	multiple	declarative	associative
15	We can use function to print the human readable form of the array.	form_r()	print_r()	display_r()	read_r()	print_r()
16	splits an array into chunks of arrays	array_ chunk()	split()	chunk()	split_chunk()	array_chunk()
17	compare arrays, and returns the differences	compare()	arr_cmp()	array_diff()	difference()	array_diff()
18	fills an array with values	fills()	array_fill()	values()	insert()	array_fill()
19	Filters the values of an array using a callback function	filter()	fill()	array_filter()	sort()	array_filter()
20	Exchanges all keys with their associated values in an array	flip()	exchange()	array()	array_flip()	array_flip()
21	function sends each value of an array to a user- made function, which returns new values	map()	array_map()	array()	fill()	array_map()

22	function merges one or more arrays into one array	merge()	join()	array_merge()	array_join()	array_merge()
23	function deletes the last element of an array	pop()	array_pop()	delete()	last()	array_pop()
24	function returns one or more random keys from an array	rand()	array_rand()	random()	array_random()	array_rand()
25	returns an array as a string, using a user-defined function	reduce()	arr_reduce()	array_ reduce()	string()	array_reduce()
26	returns an array in the reverse order	reverse()	array_ reverse()	arr_rev()	order()	array_reverse()
27	searches an array for a given value and returns the key	search()	arr_search()	array_ search()	value()	array_search()
28	Returns selected parts of an array	slice()	split()	arracy_split()	array_slice()	array_slice()
29	Returns the sum of the values in an array	sum()	array_sum()	total()	array_total()	array_sum()
30	Removes duplicate values from an array	unique()	array_ unique()		array_duplicate ()	array_unique()
31	Create array containing variables and their values	create()	variable()	compact()	value()	compact()
32	Returns the current key and value pair from an array	do()	for()	each()	while()	each()
33	Sets the internal pointer of an array to its last element	last()	end()	pointer()	element()	end()

34	Checks if a specified value exists in an array	exists()	check()	in_array()	array()	in_array()
35	Fetches a key from an array	key()	value()	array()	exists()	key()
36	Which function will return true if a variable is an array or false if it is not?	this_array()	in_array()	do_array()	is_array()	is_array()
37	Which function can be used to move the pointer to the previous array position?	previous()	prev()	last()	before()	prev()
38	In multidimensional arrays rather than a single key they values are stored in	A. Sequence of key values	2 keys	linear style	3 keys	Sequence of key values
39	PHP arrays are also called as	Vector arrays	Perl arrays	Hashes	folders	Hashes
40	PHP indexed array is also known as array.	numeric	binary	string	digital	numeric
41	PHP allows you to associate name/label with each array e	@	%	=>	#	=>
42	moves the internal pointer to the first element of the	first()	reset()	previous()	next()	reset()

Computer Technology/Information Technology Sixth Semester

FIRST INTERNAL EXAMINATION PHP PROGRAMMING

Class & Section: III B.Sc CT/ B.Sc (IT A&B)

Duration: 2 hours Maximum marks: 50 marks

Subj.Code: 16CTU601A/16ITU601A

ANSWER KEY

PART- A (20 * 1= 20 Marks) Answer ALL the Questions

1.	PHP stands for(a) Php Hypertext Process (c) Php Hypermarkup Pre	(b) Php Hyperte (d) Php Hyperma		
2.	PHP is used for building_ (a)Static (b) Dy	namic (c) No	vebsites. ne (d) A&B
3.	PHP program are run on_ (a)Web browser (b) Into	erpreter (c) We	eb server (d)Compiler
4.	PHP is devised by(a)Tim Berners- Lee		(c)Robert Caillau	(d)Richard Fairly
5.	function prints (a)echo	out information about (b)print_r()		(d)none of these
6.	PHP files have a default f (a) .html	Tile extension of(b) .xml	(c) .php	(d) .ph
7.	A PHP script should start (a) < php >			(d) php ?
8.	Which function displays (a)info()	the information about (b)sysinfo()	PHP? (c)phpinfo()	(d)php_info()
9.	PHP issc (a)Client-side		(c)Server-side	(d)Out-side
10 (a)	. Which of the below sym \r (b) \n	bols is a newline chara (c) /n) /r
11	. Which of the following s	tatements prints in PH	P?	
	(a)Out	(b)Write	(c)Echo	(d)Display
12.	In PHP, each statement m (a).(dot)	nust be end with (b); (semicolon)	(c) / (slash)	(d): (colon)

13. How to define a variable in PHP?(a)\$variable_name = value(c)\$variable_name == value;		* *	_name = value; _name as value;
14. Which of the following (a)Local	is not the scope of Va (b) Global	ariable in PHP? (c) Static	(d) Extern
15. PHP is typed l (a)Loosely	anguage. (b)Server	(c)User	(d) system
16 tells the server	which page to go to	once the user has click	the submit button on the
form. (a)Function attribute	(b)Shift attribute	(c)Action attribute	(d)none of these
17 attribute contro (a)Method attribute	ols the way that the in (b)Action attribute		ne server. (d)Function attribute
18. Which of the following (a)while	is not PHP Loops? (b)do while	(c)for	(d) do for
19. What will be the result (a)int	of combining a string (b) float	with another data type (c)string	in PHP? (d)double
20. How many data types as (a)2	re there in PHP? (b)3	(c)4	(d)5
21. What are the tools requ The three types of tools	Answer A ired for PHP Program	•	
 Tools for writing coo development enviror 		n types of tools you can	use: text editors and integrated
2. A file transfer progra	nm: It supports FTP, S	SFTP, and SCP. Easy to	use, and free.
	Install Web server so che. Run it, and start		with a control panel you can use
22. Write the syntax of PHI A PHP script can be placed		ment.	
Canonical PHP Tags:			
The script starts with <?php	and ends with ?> . Th	ese tags are also called '	Canonical PHP tags'.
A PHP script starts with p.</td <td>hp and ends with ?>:</td> <td></td> <td></td>	hp and ends with ?>:		
<u>Syntax</u>			
php</td <td></td> <td></td> <td></td>			
// PHP code goes here			
?>			

The default file extension for PHP files is ".php".

23. Difference between GET and POST Methods.

GET vs **POST** Methods

POST	GET
Values not visible in the URL	Values visible in the URL
Has not limitation of the length of the values since they are submitted via the body of HTTP	Has limitation on the length of the values usually 255 characters. This is because the values are displayed in the URL. Note the upper limit of the characters is dependent on the browser.
Has lower performance compared to Php_GET method due to time spent encapsulation the Php_POST values in the HTTP body	Has high performance compared to POST method dues to the simple nature of appending the values in the URL.
Supports many different data types such as string, numeric, binary etc.	Supports only string data types because the values are displayed in the URL
Results cannot be book marked	Results can be book marked due to the visibility of the values in the URL

PART C (3 * 8 = 24 Marks) Answer ALL the Questions

24. a) Discuss about PHP inventions and versions.

The first version of what came to be known as PHP was created in 1995 by a man named Rasmus Lerdof. Rasmus, now an engineer at Yahoo!, needed something to make it easier to create content on his web site, something that would work well with HTML, yet give him power and flexibility beyond what HTML could offer him. Essentially, what he needed was an easy way to write scripts that would run on his web server both to create content, and handle data being passed back to the server from the web browser. Using the Perl language, he created some technology that gave him what he needed and decided to call this technology "Personal Home Page/Forms Interpreter". The technology provided a convenient way to process web forms and create content.

The name "Personal Home Page/Forms Interpreter" was later shortened to PHP/FI and eventually renamed to represent "PHP: Hypertext Preprocessor". The name is said to be recursive because the full name also

includes the acronym "PHP" - an odd geeky joke that is common in technology circles when people have trouble naming things. GNU is another recursive name that represents "GNU's Not Unix".

PHP/FI version 1.0 was never really used outside of Rasmus' own web site. With the introduction of PHP/FI 2.0 this began to change. When PHP 3 was released in 1997, adoption of PHP exploded beyond all belief.

PHP 3 Hits the Big Time

By the time 1997 arrived the number of web sites on the internet was growing exponentially and most of these web sites were being implemented using the Apache web server. It was around this time that Andy Gutmans and Zeev Suraski launched the PHP 3 project, a project designed to take PHP to the next level. One of the key achievements of the PHP 3 project was to implement PHP as a robust Apache Module.

PHP 3 was implemented using a modular approach that made it easy for others to extend functionality, and also introduced the first elements of object-orientation that would continue to evolve through subsequent releases.

The combination of PHP 3 and Apache quickly lead to the widespread adoption of PHP, and it is commonly estimated that, at its peak adoption level, PHP3 was used to power over 10% of all web sites on the internet.

PHP 4 - Optimization, Scalability and More

With PHP 4 Andi Gutmans and Zeev Suraski once again re-architected PHP from the ground up. PHP 4 was built upon a piece of technology called the Zend Engine. The move to the Zend Engine brought about a number of key improvements in PHP:

- Support for other web servers (Microsoft's Internet Information Server (IIS) being of particular significance).
- Improved memory handling to avoid memory leaks (one of the most difficult types of problems to isolate in a program).
- Improved efficiency and performance to support large scale, complex, mission critical enterprise application development using PHP.

In addition PHP 4 also built on the earlier Object Oriented Programming features of PHP 3 with the introduction of classes.

PHP 5 - Object Orientation, Error Handling and XML

The main, though far from only, feature of PHP 5 is the improved support for Object Oriented Programming (OOP). In addition, PHP 5 introduced some features common in other languages such as Java like try/catch error and exception handling.

PHP 5 also introduced new extensions aimed at easing the storage and manipulation of data. Significant new features include SimpleXML for handling XML documents, and SQLite, an embedded basic and easy to use database interface.

PHP 6: In this version, ICU (International Components for Unicode) library wasembedded into the program. But due to several other reasons this version was abandoned and was not launched in the market.

PHP 7: This is the newest version of the php programming language having several features which were not present in the previous versions such as 64-bit integer support, return and scalar type declarations etc. It is powered by Zend Engine 3.

(OR)

b) How to declare a variable in PHP? What are the rules to be followed to declare the variable? A variable in PHP is a name of memory location that holds data. A variable is a temporary storage that is used to store data temporarily.

A variable can have a short name (like x and y) or a more descriptive name (age, carname, total_volume).

Rules for PHP variables:

- A variable starts with the \$ sign, followed by the name of the variable
- A variable name must start with a letter or the underscore character
- A variable name cannot start with a number
- A variable name can only contain alpha-numeric characters and underscores (A-z, 0-9, and _)
- Variable names are case-sensitive (\$age and \$AGE are two different variables)

Syntax of declaring a variable in PHP is given below:

1. \$variablename=value;

PHP VARIABLE: DECLARING STRING, INTEGER AND FLOAT

- 1. <?php
- 2. \$str="hello string";
- 3. x=200;
- 4. \$y=44.6;
- 5. echo "string is: \$str **\cdot br/\>**";
- 6. echo "integer is: \$x
";
- 7. echo "float is: \$y **\cdot br/>**";

Output:

string is: hello string integer is: 200 float is: 44.6

25. a) Write a PHP Program to displays the reverse of provided string.

```
<html>
<head>
 <title></title>
 </head>
 <body>
 <form method='POST'>
 <h2>Please input your name:</h2>
<input type="text" name="name">
<input type="submit" value="Submit Name">
</form>
<?php
//Retrieve name from query string and store to a local variable
str1 = POST['name'];
function reverse($str1) {
$n =strlen($str1);
if(n == 1)
return $str1;
else
 $n--;
return reverse(substr($str1,1, $n)) .substr($str1, 0, 1);
 }
print_r(reverse($str1));
//echo "<h3> Hello $str1 </h3>";
?>
</body>
</html>
                            (OR)
```

b) What is Operator? Explain the operators in PHP with examples. **PHP Operators**

Operators are used to perform operations on variables and values.

PHP divides the operators in the following groups:

- > Arithmetic operators
- > Assignment operators
- > Comparison operators
- > Increment/Decrement operators
- ➤ Logical operators
- > String operators
- > Array operators

PHP Arithmetic Operators

The PHP arithmetic operators are used with numeric values to perform common arithmetical operations, such as addition, subtraction, multiplication etc.

Operator	Name	Example	Result
+	Addition	\$x + \$y	Sum of \$x and \$y
-	Subtraction	\$x - \$y	Difference of \$x and \$y
*	Multiplication	\$x * \$y	Product of \$x and \$y
/	Division	\$x / \$y	Quotient of \$x and \$y
%	Modulus	\$x % \$y	Remainder of \$x divided by \$y
* *	Exponentiation	\$x ** \$y	Result of raising \$x to the \$y'th power (Introduced in PHP 5.6)

Example Program

```
<Pphp
// variable 1
$x = 29;
// variable 2
$y = 4;
// some arithmetic operations on
// these two variables
echo ($x + $y), "\n";
echo($x - $y), "\n";
echo($x * $y), "\n";
echo($x * $y), "\n";
echo($x / $y), "\n";</pre>
```

PHP Assignment Operators

The PHP assignment operators are used with numeric values to write a value to a variable.

The basic assignment operator in PHP is "=". It means that the left operand gets set to the valu of the assignment expression on the right.

Assignment	Same as	Description
x = y	x = y	The left operand gets set to the value of the expression on the right
x += y	x = x + y	Addition
x -= y	x = x - y	Subtraction
x *= y	x = x * y	Multiplication
x /= y	x = x / y	Division
x %= y	x = x % y	Modulus

Example Program

```
<?php
// simple assign operator
$y = 75;
echo $y, "\n";
// add then assign operator
$y = 100;
$y += 200;</pre>
```

```
echo $y, "\n";
// subtract then assign operator
y = 70;
$y -= 10;
echo $y, "\n";
// multiply then assign operator
y = 30;
$y *= 20;
echo $y, "\n";
// Divide then assign(quotient) operator
y = 100;
y = 5;
echo $y, "\n";
// Divide then assign(remainder) operator
y = 50;
$y %= 5;
echo $y;
>
```

PHP Comparison Operators

The PHP comparison operators are used to compare two values (number or string):

Operator	Name	Example	Result
==	Equal	\$x == \$y	Returns true if \$x is equal to \$y
===	Identical	\$x === \$y	Returns true if \$x is equal to \$y, and they are of the same type
!=	Not equal	\$x != \$y	Returns true if \$x is not equal to \$y
<> >	Not equal	\$x <> \$y	Returns true if \$x is not equal to \$y
!==	Not identical	\$x !== \$y	Returns true if \$x is not equal to \$y, or they are not of the same type
>	Greater than	\$x > \$y	Returns true if \$x is greater than \$y
<	Less than	\$x < \$y	Returns true if \$x is less than \$y

>=	Greater than or equal to	\$x >= \$y	Returns true if \$x is greater than or equal to \$y
< =	Less than or	\$ _X <= \$y	Returns true if \$x is less than or equal

Example Program

```
<php</pre>
a = 80;
b = 50;
c = 80;
// Here var_dump function has been used to
// display structured information. We will learn
// about this function in complete details in further
// articles.
var_dump(a == c) + ''n';
var_dump($a != $b) + "\n";
var_dump($a <> $b) + "\n";
var_dump(a === c) + ''n';
var_dump($a !== $c) + "\n";
var_dump(a < b) + "\n";
var_dump(a > b) + "\n";
var_dump(a \le b) + \n";
var_dump(a >= b);
 5>
```

PHP Increment / Decrement Operators

The PHP increment operators are used to increment a variable's value.

The PHP decrement operators are used to decrement a variable's value.

Operator	Name	Description
++\$x	Pre-increment	Increments \$x by one, then returns \$x
\$x++	Post-increment	Returns \$x, then increments \$x by one
\$x	Pre-decrement	Decrements \$x by one, then returns \$x
\$x	Post-decrement	Returns \$x, then decrements \$x by one

Example Program

<9php

```
$x = 2;
echo ++$x, "First increments then prints \n";
echo $x, "\n";

$x = 2;
echo $x++, "First prints then increments \n";
echo $x, "\n";

$x = 2;
echo --$x, "First decrements then prints \n";
echo $x, "\n";

$x = 2;
echo $x--, "First prints then decrements \n";
echo $x;
```

PHP Logical Operators

The PHP logical operators are used to combine conditional statements.

Operator	Name	Example	Result
and	And	\$x and \$y	True if both \$x and \$y are true
or	Or	\$x or \$y	True if either \$x or \$y is true
xor	Xor	\$x xor \$y	True if either \$x or \$y is true, but not both
&&	And	\$x && \$y	True if both \$x and \$y are true
П	Or	\$x \$y	True if either \$x or \$y is true
!	Not	!\$x	True if \$x is not true

Example Program

```
<?php
 x = 50;
y = 30;
 if (\$x == 50 \text{ and } \$y == 30)
   echo "and Success \n";
 if (\$x == 50 \text{ or } \$y == 20)
   echo "or Success \n";
if (\$x == 50 \text{ xor } \$y == 20)
  echo "xor Success \n";
 if ($x == 50 && $y == 30)
  echo "&& Success \n";
 if (\$x == 50 \mid \$y == 20)
  echo " | | Success \n";
 if (!$z)
  echo "! Success \n";
 ?>
```

PHP String Operators

PHP has two operators that are specially designed for strings.

Operator	Name	Example	Result
•	Concatenation	\$txt1.\$txt2	Concatenation of \$txt1 and \$txt2
.=	Concatenation assignment	\$txt1 .= \$txt2	Appends \$txt2 to \$txt1

Example Program

```
$\text{Php}
$x = "Geeks";
$y = "for";
$z = "Geeks!!!";
echo $x . $y . $z, "\n";
$x .= $y . $z;
echo $x;
$>
```

PHP Array Operators

The PHP array operators are used to compare arrays.

Operator	Name	Example	Result
+	Union	\$x + \$y	Union of \$x and \$y
==	Equality	\$x == \$y	Returns true if \$x and \$y have the same key/value pairs
===	Identity	\$x === \$y	Returns true if \$x and \$y have the same key/value pairs in the same order and of the same types
!=	Inequality	\$x != \$y	Returns true if \$x is not equal to \$y
<> − < > − < − < − < − < − < − < − < − <	Inequality	\$x <> \$y	Returns true if \$x is not equal to \$y
!==	Non-identity	\$x !== \$y	Returns true if \$x is not identical to \$y

Example Program

```
<Pphp
$x = array("k" => "Car", "l" => "Bike");
$y = array("a" => "Train", "b" => "Plane");
var_dump($x + $y);
var_dump($x == $y) + "\n";
var_dump($x != $y) + "\n";
var_dump($x <> $y) + "\n";
var_dump($x == $y) + "\n";
var_dump($x !== $y) + "\n";
```

Conditional or Ternary Operators

These operators are used to compare two values and take either of the result simultaneously, depending on whether the outcome is TRUE or FALSE. These are also used as shorthand notation for if...else statement that we will read in the article on decision making.

Syntax:

\$var = (condition)? value1 : value2;

Here, condition will either evaluate to true or false. If the condition evaluates to True, then value1 will be assigned to the variable \$var otherwise value2 will be assigned to it.

Operator	Name	Operation
P:	Ternary	If condition is true ? then \$x : or else \$y. This means that if condition is true then left result of the colon is accepted otherwise the result on right.

Example Program

```
<pphp
$x = -12;
echo ($x > 0) ? 'The number is positive' : 'The number is negative';
?>
```

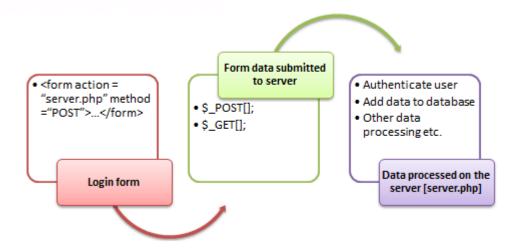

26. a) How to handle HTML form with PHP? Explain with example.

What is Form?

When you login into a website or into your mail box, you are interacting with a form.

Forms are used to get input from the user and submit it to the web server for processing.

The diagram below illustrates the form handling process.

A form is an HTML tag that contains graphical user interface items such as input box, check boxes radio buttons etc.

The form is defined using the \form\...\form\ tags and GUI items are defined using form elements such as input.

When and why we are using forms?

- Forms come in handy when developing flexible and dynamic applications that accept user input.
- Forms can be used to edit already existing data from the database

Create a form

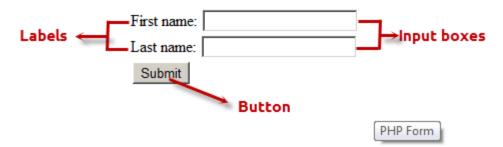

We will use HTML tags to create a form. Below is the minimal list of things you need to create a form.

- Opening and closing form tags <form>...</form>
- Form submission type POST or GET
- Submission URL that will process the submitted data
- Input fields such as input boxes, text areas, buttons, checkboxes etc.

The code below creates a simple registration form

Viewing the above code in a web browser displays the following form.

Registration Form

HERE,

- <form...>...</form> are the opening and closing form tags
- action="registration_form.php" method="POST"> specifies the destination URL and the submission type.
- First/Last name: are labels for the input boxes
- <input type="text"...> are input box tags
-
 'br'> is the new line tag
- <input type="hidden" name="form_submitted" value="1"/> is a hidden value that is used to check whether the form has been submitted or not
- <input type="submit" value="Submit"> is the button that when clicked submits the form to the server for processing

Submitting the form data to the server

The action attribute of the form specifies the submission URL that processes the data. The method attribute specifies the submission type.

PHP POST method

- This is the built in PHP super global array variable that is used to get values submitted via HTTP POST method.
- The array variable can be accessed from any script in the program; it has a global scope.
- This method is ideal when you do not want to display the form post values in the URL.
- A good example of using post method is when submitting login details to the server.

It has the following syntax.

```
<Pphp
$_POST['variable_name'];
P>
```

HERE,

• "\$ POST[...]" is the PHP array

• "'variable name'" is the URL variable name.

PHP GET method

- This is the built in PHP super global array variable that is used to get values submitted via HTTP GET method.
- The array variable can be accessed from any script in the program; it has a global scope.
- This method displays the form values in the URL.
- It's ideal for search engine forms as it allows the users to book mark the results.

It has the following syntax.

```
<?php
$_GET['variable_name'];
?>
```

HERE,

- "\$_GET[...]" is the PHP array
- "'variable_name'" is the URL variable name.

(OR)

b) Explain the looping statements in PHP with examples

In PHP, we have the following loop types:

- while loops through a block of code as long as the specified condition is true
- do...while loops through a block of code once, and then repeats the loop as long as the specified condition is true
- for loops through a block of code a specified number of times
- foreach loops through a block of code for each element in an array

PART- A (20 * 1= 20 Marks) Answer ALL the Ouestions

Answer ALL the Questions								
1.	PHP statement is e	HP statement is executed if condition is true						
	a) if-else-if-else	b) for each	c) if	d) while				
2. PHPstatement breaks the execution of current loop.								
	a) goto	b) break	c) continue	d) while				
3.	3. When the keywordexecuted inside a loop the control automatically passes to							
	beginning of loop							
	a) goto	b)break	c)switch	d) continue				
4.	is the operator of unconditional transition.							
	<i>7</i>	b) break	,	d) switch				
5.	loop should be used if number of iteration is known.							
	a) for	b) for each	c) while	d) do while				
6.	The PHP do-while loc	p is guaranteed to run	at leasttimes.					
	a)once	b)twice c)thrice		d) five				
7.	The PHP break statement breaks the execution of loop only.							
	a) inner	b) outer	c) whole program	d) none				
8.	Most complicated looping structure is							
	a)for		,	d) switch				
9.	Which one of the following PHP functions can be used to build a function that accepts any number of arguments							
		b)func_get_argc()		d)get_argc()				
10.	. Which one of the following PHP functions can be used to find files?							
	a)glob()	b)file()	c)fold()	d)get_file()				
11.	1. The filesize() function returns the file size in							
	a)bits	b)bytes	, ·	d) gigabytes				
12. Which one of the following PHP function is used to determine a file's last access time?								
	, ,,	b)filectime()	,	d)filetime()				
13.	Which one of the following function is capable of reading a file into an array?							
	a)file()	b)arrfile()	c)arr_file()	d)file_arr()				

15. All these func_num_args (), func_get_arg (), func_get_args (), functions are introduced in a)PHP1 b)PHP2 c)PHP3 d)PHP4 16. PHP function arguments are modified in function definition and a)In a function call b)In execution time c)In deceleration time d)None of them 17 scope refers to any variable that is defined outside of any function a)Local b)Global c)Static d) parameters 18. A parameter is a variable whose value is passed to the function by the calling code. a)Local b)Global c)Static d) parameters 19. A static variable is again a variable with scope a)Global b)Static c) parameters d) local 20. The represents reference of the variable. a)\$ b)& c)* d)@ PART B (3 * 2 = 6 Marks) Answer ALL the Questions 21. What is the difference between do-while and while - do? Entry controlled loop while-do Exit controlled loop do-while 22. Define Function. Functions are basically named scripts that can be called upon from any other script to perform a	14.	14. The function func_num_args() returns a) the number of arguments passed to the function b) the total length of the arguments c) the number of lines in the program d) the number of variables used in the program								
16. PHP function arguments are modified in function definition and a)In a function call b)In execution time c)In deceleration time d)None of them 17 scope refers to any variable that is defined outside of any function a)Local b)Global c)Static d) parameters 18. }										

PART C (3 * 8 = 24 Marks) Answer ALL the Questions

24. a) Explain in detail about conditional statements in PHP with example.

PHP Conditional Statements

Conditional statements are used to perform different actions based on different conditions.

In PHP we have the following conditional statements:

- 1. if statement executes some code if one condition is true
- 2. if...else statement executes some code if a condition is true and another code if that condition is false
- 3. if...elseif....else statement executes different codes for more than two conditions
- 4. switch statement selects one of many blocks of code to be executed

PHP - The if Statement

The if statement executes some code if one condition is true.

```
Syntax

if (condition) {
	code to be executed if condition is true;
}

The example below will output "Have a good day!" if the current time (HOUR) is less than 20:

Example
<pphp
$t = date("H");

if ($t < "20") {
	echo "Have a good day!";
}

>>
```

PHP - The if...else Statement

The if....else statement executes some code if a condition is true and another code if that condition is false.

```
Syntax
if (condition) {
  code to be executed if condition is true;
} else {
  code to be executed if condition is false;
}
```

The example below will output "Have a good day!" if the current time is less than 20, and "Have a good night!" otherwise:

Example

```
<?php
$t = date("H");

if ($t < "20") {
    echo "Have a good day!";
} else {
    echo "Have a good night!";
}
</pre>
```

PHP - The if...elseif....else Statement

The if....else if...else statement executes different codes for more than two conditions.

```
Syntax
if (condition) {
   code to be executed if this condition is true;
} elseif (condition) {
   code to be executed if this condition is true;
} else {
   code to be executed if all conditions are false;
}
```

The example below will output "Have a good morning!" if the current time is less than 10, and "Have a good day!" if the current time is less than 20. Otherwise it will output "Have a good night!":

```
Example
<pphp
$t = date("H");

if ($t < "10") {
    echo "Have a good morning!";
} elseif ($t < "20") {
    echo "Have a good day!";
}</pre>
```

```
} else {
    echo "Have a good night!";
}
```

PHP - The switch Statement

The switch statement is used to perform different actions based on different conditions.

The PHP switch Statement

Use the switch statement to select one of many blocks of code to be executed.

```
Syntax
switch (n) {
    case label1:
        code to be executed if n=label1;
        break;
    case label2:
        code to be executed if n=label2;
        break;
    case label3:
        code to be executed if n=label3;
        break;
    ...
    default:
        code to be executed if n is different from all labels;
}
```

This is how it works: First we have a single expression n (most often a variable), that is evaluated once. The value of the expression is then compared with the values for each case in the structure. If there is a match, the block of code associated with that case is executed. Use break to prevent the code from running into the next case automatically. The default statement is used if no match is found.

Example

```
<?php
$favcolor = "red";
switch ($favcolor) {
  case "red":
     echo "Your favorite color is red!";
     break;
  case "blue":
     echo "Your favorite color is blue!";
     break;
  case "green":
     echo "Your favorite color is green!";
     break;
  default:
     echo "Your favorite color is neither red, blue, nor green!";
}
5>
```

(Or)

b) Discuss on different types of looping statements in PHP.

PHP Loops

Often when you write code, you want the same block of code to run over and over again in a row. Instead of adding several almost equal code-lines in a script, we can use loops to perform a task like this.

In PHP, we have the following looping statements:

- 1. while loops through a block of code as long as the specified condition is true
- 2. do...while loops through a block of code once, and then repeats the loop as long as the specified condition is true
- 3. for loops through a block of code a specified number of times
- 4. foreach loops through a block of code for each element in an array

The PHP while Loop

The while loop executes a block of code as long as the specified condition is true.

```
Syntax
```

```
while (condition is true) {
  code to be executed;
}
```

The example below first sets a variable x = 1. Then, the while loop will continue to run as long as x = 1. Then, or equal to x = 1. x = 1. Then, the while loop runs (x = 1):

Example

```
<Pphp
$x = 1;

while($x <= 5) {
    echo "The number is: $x <br>";
    $x++;
}
```

do...while Loop

The do...while loop will always execute the block of code once, it will then check the condition, and repeat the loop while the specified condition is true.

Syntax

```
do {
   code to be executed;
} while (condition is true);
```

The example below first sets a variable x to 1 (x = 1). Then, the do while loop will write some output, and then increment the variable x with 1. Then the condition is checked (is x less than, or equal to x), and the loop will continue to run as long as x is less than, or equal to x:

```
Example
```

```
<?php
```

```
x = 1;
```

```
do {
    echo "The number is: $x <br>";
    $x++;
} while ($x <= 5);
</pre>
```

do while loop the condition is tested AFTER executing the statements within the loop. This means that the do while loop would execute its statements at least once, even if the condition is false the first time.

The example below sets the \$x variable to 6, then it runs the loop, and then the condition is checked:

Example

```
<?php
$x = 6;
do {
   echo "The number is: $x <br>";
   $x++;
} while ($x <= 5);
</pre>
```

The PHP for Loop

The for loop is used when you know in advance how many times the script should run.

Syntax

```
for (init counter; test counter; increment counter) {
  code to be executed;
}
```

Parameters:

- init counter: Initialize the loop counter value
- ➤ test counter: Evaluated for each loop iteration. If it evaluates to TRUE, the loop continues. If it evaluates to FALSE, the loop ends.
- increment counter: Increases the loop counter value
- \triangleright The example below displays the numbers from 0 to 10:

```
Example
<Pphp
for ($x = 0; $x <= 10; $x++) {
    echo "The number is: $x <br>";
}
P>
```

PHP foreach Loop

The foreach loop works only on arrays, and is used to loop through each key/value pair in an array.

Syntax

```
foreach ($array as $value) {
  code to be executed;
}
```

For every loop iteration, the value of the current array element is assigned to \$value and the array pointer is moved by one, until it reaches the last array element.

The following example demonstrates a loop that will output the values of the given array (\$colors):

Example

```
<Pphp
$colors = array("red", "green", "blue", "yellow");
foreach ($colors as $value) {
   echo "$value <br>";
}
```

25. a) Explain in detail about PHP Function with arguments with example program PHP Function Arguments
Information can be passed to functions through arguments. An argument is just like a variable.

Arguments are specified after the function name, inside the parentheses. You can add as many arguments as you want, just separate them with a comma.

The following example has a function with one argument (\$fname). When the familyName() function is called, we also pass along a name (e.g. Jani), and the name is used inside the function, which outputs several different first names, but an equal last name:

```
Example
<?php
function familyName($fname) {
  echo "$fname Refsnes.<br>";
}
familyName("Jani");
familyName("Hege");
familyName("Stale");
familyName("Kai Jim");
familyName("Borge");
?>
The following example has a function with two arguments ($fname and $year):
<?php
function familyName($fname, $year) {
  echo "$fname Refsnes. Born in $year <br>";
familyName("Hege", "1975");
familyName("Stale", "1978");
familyName("Kai Jim", "1983");
?>
PHP Default Argument Value
The following example shows how to use a default parameter. If we call the function setHeight()
without arguments it takes the default value as argument:
Example
<?php
function setHeight($minheight = 50) {
  echo "The height is: $minheight <br>";
}
setHeight(350);
setHeight(); // will use the default value of 50
setHeight(135);
setHeight(80);
?>
```

Function argument with call by value

Call by value means passing the value directly to a function. The called function uses the value in a local variable; any changes to it do not affect the source variable. Example

This is a "global", or automatic global, variable. This simply means that it is available in all scopes throughout a script. There is no need to do global \$x; to access it within functions or methods.

```
<?php
//Call by value program
function abc($x)
{
  $x=$x+10;
  return($x);
  }
  $a=20;
  echo abc($a)."<br>";
  echo ($a);
  ?>
```

Note: Call by value: in the call by value method, the called function creates a new set of variables and copies the values of arguments into them.

Function argument with call by reference

Call by reference means passing the address of a variable where the actual value is stored. The called function uses the value stored in the passed address; any changes to it do affect the source variable.

```
<?php
//call by reference program in php
function abc($x)
{
    $x=$x-10;
    return($x);
}
    $a=50;
    echo abc($a)."<br>";
    echo ($a);
}
```

Note: Call by reference: in the call by reference method, instead of passing a value to the function being called a reference/pointer to the original variable is passed.

(Or)

b) Elucidate on Scope of Function in Global and Local.

SCOPE OF FUNCTION GLOBAL AND LOCAL

- 1. Variables declared outside of functions and classes are global. Global variables are available else where in the script.
- 2. Function variables are self-contained and do not affect variables in the main script.
- 3. Variables from the main script are not implicitly made available inside functions.

Example

Take a look at this example:

<PPHP function foo() { \$bar = "java2s.com"; } \$bar = "PHP"; foo(); print \$bar; P>

The code above generates the following result.

PHP

- Execution of the script starts at the \$bar = "PHP" line, and then calls the foo() function.
- > foo() sets \$bar to java2s.com, then returns control to the main script where \$bar is printed out.
- > Function foo() is called, and, having no knowledge that a \$bar variable exists in the global scope, creates a \$bar variable in its local scope.
- > Once the function ends, all local scopes are gone, leaving the original \$bar variable intact.

PHP Global Variables

A global variable can be accessed anywhere in your script, whether inside or outside a function.

In PHP, all variables created outside a function are, in a sense, global in that they can be accessed by any other code in the script that's not inside a function.

To use such a variable inside a function, write the word global followed by the variable name inside the function's code block.

<?PHP

5>

```
$myGlobal = "Hello there!";

function hello() {
    global $myGlobal;
    echo "$myGlobal\n";
}

hello(); // Displays "Hello there!"
```

The code above generates the following result.

Hello there!

hello() function accesses the \$myGlobal variable by declaring it to be global using the global statement. The function can then use the variable to display the greeting.

Example 1

Created a variable outside a function to use it as a global variable. Take a look at the following script: <PHP

```
function setup() {
    global $myGlobal;
    $myGlobal = "Hello there!";
}
function hello() {
    global $myGlobal;
    echo "$myGlobal\n";
}
setup();
hello(); // Displays "Hello there!"
P>
```

The code above generates the following result.

Hello there!

In this script, the setup() function is called first. It declares the \$myGlobal variable as global, and gives it a value.

Then the hello() function is called. It too declares \$myGlobal to be global, which means it can now access its value previously set by setup() and display it.

Example 2

The \$GLOBALS array can access global variables within functions. All variables declared in the global scope are in the \$GLOBALS array, which you can access anywhere in the script. Here is a demonstration:

```
<PPHP
function foo() {
  $GLOBALS['bar'] = "java2s.com";</pre>
```

```
}
   bar = "PHP";
   foo();
   print $bar;
   5>
   The code above generates the following result.
   java2s.com
   We can read variables in the same way:
   $localbar = $GLOBALS['bar'];
   PHP GLOBAL keyword allow a variable to be accessed locally.
   function myfunc() {
      GLOBAL $foo, $bar, $baz;
      ++$baz;
   }
   The code above reads the global variables $foo, $bar, and $baz. The ++$baz line will increment $baz
   by 1, and this will be reflected in the global scope.
26. . a) Explain String manipulation and commands with example program.
                                 (Or)
      b) Explain the following with an example
       (i) preg_match()
                              (ii) preg_replace ()
```

(ii) preg_split ()
