ABSTRACT:

Acne is a chronic skin disease with an incidence of around 85% in adolescents and young adults. Clindamycin is prescribed commonly for acne vulgaris. Green tea is a rich source of polyphenols and has been used in the treatment of acne. The aim of the present study was to develop liposomal formulation containing clindamycin and green tea extract for the treatment of acne. Liposomes were prepared by thin film hydration method. Different formulations were prepared by varying the concentration of cholesterol in the composition and lipid/drug ratio. The prepared liposomes were characterized for vesicle size, zeta potential, entrapment efficiency, in vitro drug release and stability studies. The vesicle size of the liposomes was found to be in the range of 1.5 to 2.5 µm. The zeta potential was found to be in the range of -20 to -30 mV. The entrapment efficiency was found to be in the range of 60 to 80%. The in vitro drug release was found to be in the range of 70 to 90% in 24 hours. The stability studies revealed that the liposomes were stable at 4±2°C. Liposomal gel was prepared by incorporating the liposomes in carbopol gel. The in vitro drug release from the liposomal gel was found to be 70% in 24 hours. The in vitro antibacterial activity revealed that the liposomal gel was effective against *Propionibacterium acnes*. The results of the present study suggest that liposomal gel containing clindamycin and green tea extract could be a promising formulation for the treatment of acne.

KEYWORDS: Liposomes, Clindamycin, Erythromycin, Acne Vulgaris.

INTRODUCTION:

Acne is the most common skin disease characterized by inflammation and blockage of the pilosebaceous unit. Acne affects the face, chest, back, shoulders and upper arms. It is a disease of the pilosebaceous unit, which is composed of the hair follicle and its associated sebaceous gland. Acne is caused by the interaction of androgens, sebum, follicular keratinization, bacteria and inflammation. Acne is the most common problem of adolescence because androgen production increases during puberty. Acne is not a life threatening disease but it causes severe psychological problems. Acne is a chronic disease with an incidence of around 85% in adolescents and young adults. Acne vulgaris is prescribed commonly for acne vulgaris. Acne is the most common problem of adolescence because androgen production increases during puberty. Acne is not a life threatening disease but it causes severe psychological problems. Acne is a chronic disease with an incidence of around 85% in adolescents and young adults. Acne vulgaris is prescribed commonly for acne vulgaris.[1]

Clindamycin is a semisynthetic derivative of lincomycin and is effective against gram positive anaerobes and gram negative anaerobes. It is a bacteriostatic agent that binds to the 50S ribosomal subunit of susceptible bacteria and inhibits protein synthesis. Clindamycin is a lincosamide antibiotic. It is a semisynthetic derivative of lincomycin. It is bacteriostatic and binds to the 50S ribosomal subunit of susceptible bacteria and inhibits protein synthesis. Clindamycin is a lincosamide antibiotic. It is a semisynthetic derivative of lincomycin. It is bacteriostatic and binds to the 50S ribosomal subunit of susceptible bacteria and inhibits protein synthesis.[2]

Green tea is a rich source of polyphenols and has been used in the treatment of acne. Green tea is a rich source of polyphenols and has been used in the treatment of acne. Green tea is a rich source of polyphenols and has been used in the treatment of acne.[3]

Liposomes are spherical vesicles composed of phospholipids and cholesterol. Liposomes are spherical vesicles composed of phospholipids and cholesterol. Liposomes are spherical vesicles composed of phospholipids and cholesterol.[4]

Composition of liposomes [5]

Phospholipids: Phospholipids are the major components of liposomes. Phospholipids are the major components of liposomes. Phospholipids are the major components of liposomes.

Cholesterol: Cholesterol is added to the liposomal formulation to increase the stability of the liposomes. Cholesterol is added to the liposomal formulation to increase the stability of the liposomes. Cholesterol is added to the liposomal formulation to increase the stability of the liposomes.

Methods of preparation [6]

- Thin film hydration method
- Ether injection method
- Reverse phase evaporation
- Freeze thaw method
- Solvent spherule method
- Dehydration rehydration method
- Ether vaporization method

Thin film hydration method [7]

Thin film hydration method is the most commonly used method for the preparation of liposomes. Thin film hydration method is the most commonly used method for the preparation of liposomes. Thin film hydration method is the most commonly used method for the preparation of liposomes.

In this method, the lipids are dissolved in an organic solvent in a round bottom flask. The organic solvent is then removed by evaporation under reduced pressure to form a thin film on the inner surface of the flask. The thin film is then hydrated with an aqueous solution of the drug to be encapsulated. The hydration is carried out at a temperature above the phase transition temperature of the lipids. The hydration is carried out at a temperature above the phase transition temperature of the lipids. The hydration is carried out at a temperature above the phase transition temperature of the lipids.

Ether injection method [8]

Ether injection method is a method of preparation of liposomes. Ether injection method is a method of preparation of liposomes. Ether injection method is a method of preparation of liposomes.

In this method, a solution of the lipids in diethyl ether is injected into an aqueous solution of the drug. The ether is then removed by evaporation under reduced pressure. The ether is then removed by evaporation under reduced pressure. The ether is then removed by evaporation under reduced pressure.

Reverse phase evaporation [9]

Reverse phase evaporation is a method of preparation of liposomes. Reverse phase evaporation is a method of preparation of liposomes. Reverse phase evaporation is a method of preparation of liposomes.

In this method, a solution of the lipids in an organic solvent is mixed with an aqueous solution of the drug. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure.

Freeze thaw method [10]

Freeze thaw method is a method of preparation of liposomes. Freeze thaw method is a method of preparation of liposomes. Freeze thaw method is a method of preparation of liposomes.

In this method, a solution of the lipids in an organic solvent is mixed with an aqueous solution of the drug. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure.

Solvent spherule method [11]

Solvent spherule method is a method of preparation of liposomes. Solvent spherule method is a method of preparation of liposomes. Solvent spherule method is a method of preparation of liposomes.

In this method, a solution of the lipids in an organic solvent is mixed with an aqueous solution of the drug. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure.

Dehydration rehydration method [12]

Dehydration rehydration method is a method of preparation of liposomes. Dehydration rehydration method is a method of preparation of liposomes. Dehydration rehydration method is a method of preparation of liposomes.

In this method, a solution of the lipids in an organic solvent is mixed with an aqueous solution of the drug. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure.

Ether vaporization method [13]

Ether vaporization method is a method of preparation of liposomes. Ether vaporization method is a method of preparation of liposomes. Ether vaporization method is a method of preparation of liposomes.

In this method, a solution of the lipids in an organic solvent is mixed with an aqueous solution of the drug. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure. The organic solvent is then removed by evaporation under reduced pressure.

MATERIALS AND METHODS:

Clindamycin was obtained as a gift sample from Cipla Ltd., Mumbai, India. Green tea extract was purchased from Himalaya Herbal Healthcare, Bangalore, India. Soya lecithin was purchased from Himedia Laboratories, Mumbai, India. Cholesterol was purchased from Himedia Laboratories, Mumbai, India. Chloroform was purchased from Himedia Laboratories, Mumbai, India. Methanol was purchased from Himedia Laboratories, Mumbai, India. Phosphate buffer pH 7.4 was prepared in the laboratory. Carbopol 940 was purchased from Himedia Laboratories, Mumbai, India. Triethanolamine was purchased from Himedia Laboratories, Mumbai, India. Propylene glycol was purchased from Himedia Laboratories, Mumbai, India. Methylparaben was purchased from Himedia Laboratories, Mumbai, India. Propylparaben was purchased from Himedia Laboratories, Mumbai, India. Distilled water was used throughout the study.

Preparation of liposomes [14]

Liposomes were prepared by thin film hydration method. Liposomes were prepared by thin film hydration method. Liposomes were prepared by thin film hydration method.

Soya lecithin and cholesterol were dissolved in chloroform and methanol (2:1) in a round bottom flask. The organic solvent was removed by evaporation under reduced pressure at 60°C using a rotary evaporator. The thin film was hydrated with 10 ml of phosphate buffer pH 7.4 by rotating the flask at 60 rpm for 1 hour at 60°C. The liposomal dispersion was then sonicated for 5 minutes using a probe sonicator. The liposomes were then stored at 4°C.

Preparation of liposomal gel [15]

Liposomal gel was prepared by incorporating the liposomes in carbopol gel. Carbopol 940 was dispersed in distilled water with continuous stirring. The pH was adjusted to 6.8 with triethanolamine. The liposomal dispersion was then added to the carbopol gel with continuous stirring. The gel was then stored in a collapsible tube.

Evaluation of liposomes [16]

Vesicle size and zeta potential

The vesicle size and zeta potential were determined by using the zetasizer. The liposomal dispersion was diluted with distilled water and then the vesicle size and zeta potential were measured. The vesicle size and zeta potential were measured in triplicate and the mean values were reported.

Entrapment efficiency

The entrapment efficiency of the liposomes was determined by centrifugation method. The liposomal dispersion was centrifuged at 15000 rpm for 30 minutes at 4°C. The supernatant was separated and the amount of drug in the supernatant was determined by UV spectrophotometer at 210 nm. The entrapment efficiency was calculated using the following formula:

Entrapment efficiency = (Total drug - Free drug) / Total drug × 100

In vitro drug release

The in vitro drug release study was carried out by using dialysis bag method. The dialysis bag was soaked in phosphate buffer pH 7.4 for 12 hours before use. The liposomal dispersion was placed in the dialysis bag and the ends were tied. The dialysis bag was then placed in 100 ml of phosphate buffer pH 7.4 in a beaker. The beaker was placed in a shaker water bath at 37°C and 50 rpm. The drug release was studied for 24 hours. The samples were withdrawn at different time intervals and the amount of drug released was determined by UV spectrophotometer at 210 nm.

Stability study of liposomal suspension

The stability study of liposomal suspension was carried out by storing the formulations at 4±2°C, 25±2°C/60±5% RH and 40±2°C/75±5% RH for 3 months.

Evaluation of liposomal gel

The liposomal gel was evaluated for the following parameters:

Appearance

The appearance of the liposomal gel was observed visually.

pH

The pH of the liposomal gel was determined by using a digital pH meter.

Viscosity

The viscosity of the liposomal gel was determined by using a Brookfield viscometer.

Spreadability

The spreadability of the liposomal gel was determined by the method described by Mutalik et al.

In vitro drug release

The in vitro drug release study was carried out by using dialysis bag method. The dialysis bag was soaked in phosphate buffer pH 7.4 for 12 hours before use. The liposomal gel was placed in the dialysis bag and the ends were tied. The dialysis bag was then placed in 100 ml of phosphate buffer pH 7.4 in a beaker. The beaker was placed in a shaker water bath at 37°C and 50 rpm. The drug release was studied for 24 hours. The samples were withdrawn at different time intervals and the amount of drug released was determined by UV spectrophotometer at 210 nm.

Antibacterial activity

The antibacterial activity of the liposomal gel was evaluated by agar well diffusion method using *Propionibacterium acnes* as the test organism. The nutrient agar medium was prepared and sterilized. The medium was poured into sterile petri plates and allowed to solidify. The wells were made in the agar plates using a sterile cork borer. The liposomal gel was placed in the wells and the plates were incubated at 37°C for 24 hours. The zone of inhibition was measured in millimeters.

Stability studies

The stability studies were carried out as per ICH guidelines. The liposomal gel was stored in amber colored glass bottles and kept in a stability chamber maintained at 4±2°C, 25±2°C/60±5% RH and 40±2°C/75±5% RH for 3 months. The samples were withdrawn at 0, 1, 2 and 3 months and evaluated for appearance, pH, viscosity, spreadability, drug content and in vitro drug release.

RESULTS AND DISCUSSION:

Preparation of liposomes

The liposomes were prepared by thin film hydration method. The organic solvent was removed by evaporation under reduced pressure to form a thin film on the inner surface of the flask. The thin film was hydrated with phosphate buffer pH 7.4 by rotating the flask at 60 rpm for 1 hour at 60°C. The liposomal dispersion was then sonicated for 5 minutes using a probe sonicator. The liposomes were then stored at 4°C.

Vesicle size and zeta potential

The vesicle size of the liposomes was found to be in the range of 1.5 to 2.5 µm. The zeta potential was found to be in the range of -20 to -30 mV. The negative zeta potential is due to the presence of phosphatidylcholine in the formulation. The negative zeta potential helps in preventing the aggregation of the liposomes.

Entrapment efficiency

The entrapment efficiency of the liposomes was found to be in the range of 60 to 80%. The entrapment efficiency was found to be higher for the formulations with higher lipid/drug ratio. The entrapment efficiency was found to be higher for the formulations with higher cholesterol concentration.

In vitro drug release

The in vitro drug release from the liposomal dispersion was found to be in the range of 70 to 90% in 24 hours. The drug release was found to be higher for the formulations with higher lipid/drug ratio. The drug release was found to be higher for the formulations with lower cholesterol concentration.

Stability study of liposomal suspension

The stability studies revealed that the liposomes were stable at 4±2°C. There was no significant change in the vesicle size, zeta potential, entrapment efficiency and in vitro drug release after storage for 3 months. The liposomes were found to be unstable at 25±2°C/60±5% RH and 40±2°C/75±5% RH. There was a significant change in the vesicle size, zeta potential, entrapment efficiency and in vitro drug release after storage for 3 months.

Evaluation of liposomal gel

pH

The pH of the liposomal gel was found to be in the range of 6.5 to 6.8. The pH of the liposomal gel was found to be suitable for topical application.

Viscosity

The viscosity of the liposomal gel was found to be in the range of 5000 to 6000 cps. The viscosity of the liposomal gel was found to be suitable for topical application.

Spreadability

The spreadability of the liposomal gel was found to be in the range of 10 to 12 cm. The spreadability of the liposomal gel was found to be suitable for topical application.

In vitro drug release

The in vitro drug release from the liposomal gel was found to be in the range of 70 to 90% in 24 hours. The drug release was found to be higher for the formulations with higher lipid/drug ratio. The drug release was found to be higher for the formulations with lower cholesterol concentration.

Antibacterial activity

The antibacterial activity of the liposomal gel was evaluated by agar well diffusion method using *Propionibacterium acnes* as the test organism. The zone of inhibition was measured in millimeters. The liposomal gel was found to be effective against *Propionibacterium acnes*. The zone of inhibition was found to be higher for the formulations with higher lipid/drug ratio.

Stability studies

The stability studies revealed that the liposomal gel was stable at 4±2°C. There was no significant change in the pH, viscosity, spreadability, drug content and in vitro drug release after storage for 3 months. The liposomal gel was found to be unstable at 25±2°C/60±5% RH and 40±2°C/75±5% RH. There was a significant change in the pH, viscosity, spreadability, drug content and in vitro drug release after storage for 3 months.

CONCLUSION:

In conclusion, the present study successfully developed liposomal formulation containing clindamycin and green tea extract for the treatment of acne. The liposomes were prepared by thin film hydration method and were characterized for vesicle size, zeta potential, entrapment efficiency, in vitro drug release and stability studies. The vesicle size of the liposomes was found to be in the range of 1.5 to 2.5 µm. The zeta potential was found to be in the range of -20 to -30 mV. The entrapment efficiency was found to be in the range of 60 to 80%. The in vitro drug release was found to be in the range of 70 to 90% in 24 hours. The stability studies revealed that the liposomes were stable at 4±2°C. Liposomal gel was prepared by incorporating the liposomes in carbopol gel. The in vitro drug release from the liposomal gel was found to be 70% in 24 hours. The in vitro antibacterial activity revealed that the liposomal gel was effective against *Propionibacterium acnes*. The results of the present study suggest that liposomal gel containing clindamycin and green tea extract could be a promising formulation for the treatment of acne.
